## **Abstract**

**Background:**-The WHO Expert Committee on the Role of Hospitals at the First Referral Level identified the key problems within the referral system are over- loading of hospitals with inappropriate self- referrals, poorly-judged referrals, leading to by-passing of those levels and inadequate flow of information to and from the hospital.

**Objective:** - The purpose of this study is to assess magnitude and determinants of self-referral of patient at Nekemte General Hospital, East wollega, Ethiopia, 2014.

**Method and materials:** A hospital based cross sectional study was conducted from April 16-30, 2014. Four hundred twenty two patients attending Nekemte hospital were selected using systematic sampling technique. Data were collected using structured and pre-tested questionnaire. Six data collectors and one supervisor were trained and involved in the data collection process. Data were entered and analyzed with bivariate and multivariate logistic regression using SPSS version 20.0-computer software.

**Result:** Response rate was 99.8%. A total 346 (82%) of respondents at Nekemte general hospital were self-referred. Among respondents 218(51.7%) were female. Patients who knew closer health facility as the first referral were 76% less likely to self refer themselves to the Nekemte General Hospital as compared with those who did not know it. Those who obtained information on the referral system from health worker were 35% less likely to self refer themselves to Nekemte General Hospital.

**Conclusion and Recommendation:** obtaining laboratory test service, drug at closer health facility, knowing the closer health facility as first referral level and the obtaining of health education on referral system from health worker were found to be significantly associated with self-referral to Nekemte General Hospital. Ensuring primary level health care particularly health centers with adequate drug supply and laboratory services, health workers should take measures to improve awareness of patient on referral system.

Key word: self-referral, Nekemte, Ethiopia.

## **Acknowledgements**

I would like to thank my advisors Mr. Waju Beyene and Mr. Gebeyehu Tsega for the very detail, exhaustive and constructive comments and advices they gave me for the preparation of this report and in advance for their willing in helping and giving valuable comments in the subsequent time and Jimma University, College of public health and medical sciences.

My sincere gratitude goes to all data collectors, supervisors, data manager and study participants whose contribution was vital to go through the data collection work.

I would like to thank the Nekemte general hospital manager and the medical director for their permission to conduct the study in the facility.

Special thanks to my family; my father Ato Olani Abdi , my mother W/ro Dalesso Nikus and also to W/ro Chaltu Degeffa.

## Acronyms & Abbreviations

CHF	closer health facility
E/W ZHD	East Wollega Zonal Health Department
FLCF	First level care facility

Investigator , April 2014.....5

## **Chapter 1: Introduction**

### **1.1 Background:**

Referral is a process by which a health worker transfers the responsibility of care temporarily or permanently to another health professional or social worker or to the community to obtain the consultation or special expertise directly needed (1). Referral system is a support system that assists in making health services more effective, efficient, and equitable to its users and it is very important in maximizing limited resources, avoiding duplication of services, promoting cooperation and complementation of primary, secondary and tertiary health facilities and in promoting continuity of treatment and ensuring sustainability of the service. Referral can be one way or both ways. The most common is the two ways (bidirectional) in which all involved organizations will refer clients to receive available comprehensive care, treatment and support (2).

Referral support is important to the proper functioning of first level health facilities in a health system based on primary health care. The proper functioning of the first level service, which is composed of health posts, health centers and primary hospital, is a guarantee for equity of accessibility to secondary and tertiary level health care and can prevent over use of these higher-level health care facilities (3).

The universal access to health care can be achieved through provision of quality health care service to people living in rural and remote areas(4). Unlike rural, urban areas are better served in terms of distance to health care facility, health worker density and quality of care, compared with remote areas (5). One of the primary ways to improve services in remote regions is through an effective and efficient referral system. Referrals have considerable implications for patient outcomes, the healthcare system and healthcare costs (6, 7).

Different countries have different referral structures according to their health policy to implement effective referral mechanism. Despite referral structure, there may be situations where people by-pass a primary level health care which decreases the efficiency of specialty care system, and leads to problems for the individual and the

healthcare system, such as: accrual of unnecessary costs to the system , payment difficulties for the patient, lack of comprehensive healthcare information for the patient, lack of planned referral and its benefits of continuity of care, lowered standards of specialist care due to overburdening, compromising the established referral system, reduction in feedback and follow up after treatment procedures (8,9).

Ethiopia is among the developing nations located in Sub- Saharan Africa. To improve access to health services, the government, which is the main provider and financer of health care, has established a three-tier health service delivery system, which requires an effective two-way referral connections (10). The country health policy which was issued in 1993 has also got strategy in the development of an effective referral system by: improving accessibility of care according to need, assuring continuity and improved quality of care at all levels, rationalizing costs for health care seekers and providers for optimal utilization of health care facilities at all levels and strengthening the communication within the healthcare system (11).

## **1.2 STATEMENT OF THE PROBLEM**

Patient referral system is practiced in developed and developing countries with differing levels of quality and care according to their socioeconomic status, availability of resources and organization of services. According to the World Health Organization expert committee on the role of hospitals at the first referral level identified the key problems within the referral system includes over- loading of hospitals with self-referred patients, poorly judged referrals, lack of confidence in health care at the health post/ centers levels leading many patients to bypass them to the higher level for minor health problem (12).

Self-referrals may cause the primary level health care being under-utilized, and hospitals being over used, congested and overburdened, leading to an escalation of health care costs. It makes many patients spend long waiting hours to see highly trained medical workers in hospitals and misapplication of the highly trained health workers' time, which causes inadequate flow of information to and from the hospital. Due to large patient loads, human and physical resources are stretched to capacity, which results in hospitals compromising the care that they provide to patients, who genuinely and correctly deserve to be managed in a specialized care setting (13-15).

Provision of primary care at the hospital distorts its function. It is believed many of the apparent shortcomings of the hospitals are linked to congested outpatient departments and overworked laboratories performing hundreds of routine tests. Overqualified staff and expensive facilities are therefore used in ways their planners did not contemplate. It is good to ensure that hospitals concentrate on their roles as referral centers and not made to perform the functions of health centers (16).

In Ethiopia there is the recent accelerated expansion of primary health care facilities, the Ethiopian health system seems to have addressed one of the most significant barriers to entry to the health system, the availability of basic care within a reasonable distance (18). However, there are still significant gaps between the level of coverage within the facilities and the utilization of the available services. Therefore, it is high time that proper attention be given to quality in the delivery of health services. The reasons for the gap between the availability of health services and the level of utilization health services by

the population need to be explored and identified. Otherwise, the underutilization of services at most peripheral public facilities tend to continue, while at the same time patients incur unnecessary costs due to self-referral to distant and more expensive centers. This again will result in wastage and inefficiency of resources, in addition to negatively affecting the overall efforts and investments of decreasing morbidity and mortality for improving health status among the country's population (19). From my experience, observation, and review with experts at Nekemte General Hospital most patients came to the hospital without referral paper for their health problem but the magnitude and determinants self-referral of patients not yet identified.

These have motivated and increase the interest of the researcher to assess the magnitude and associated determinants. Therefore, this study aimed to assess the magnitude and determinants of self-referral of patient to the secondary referral level.

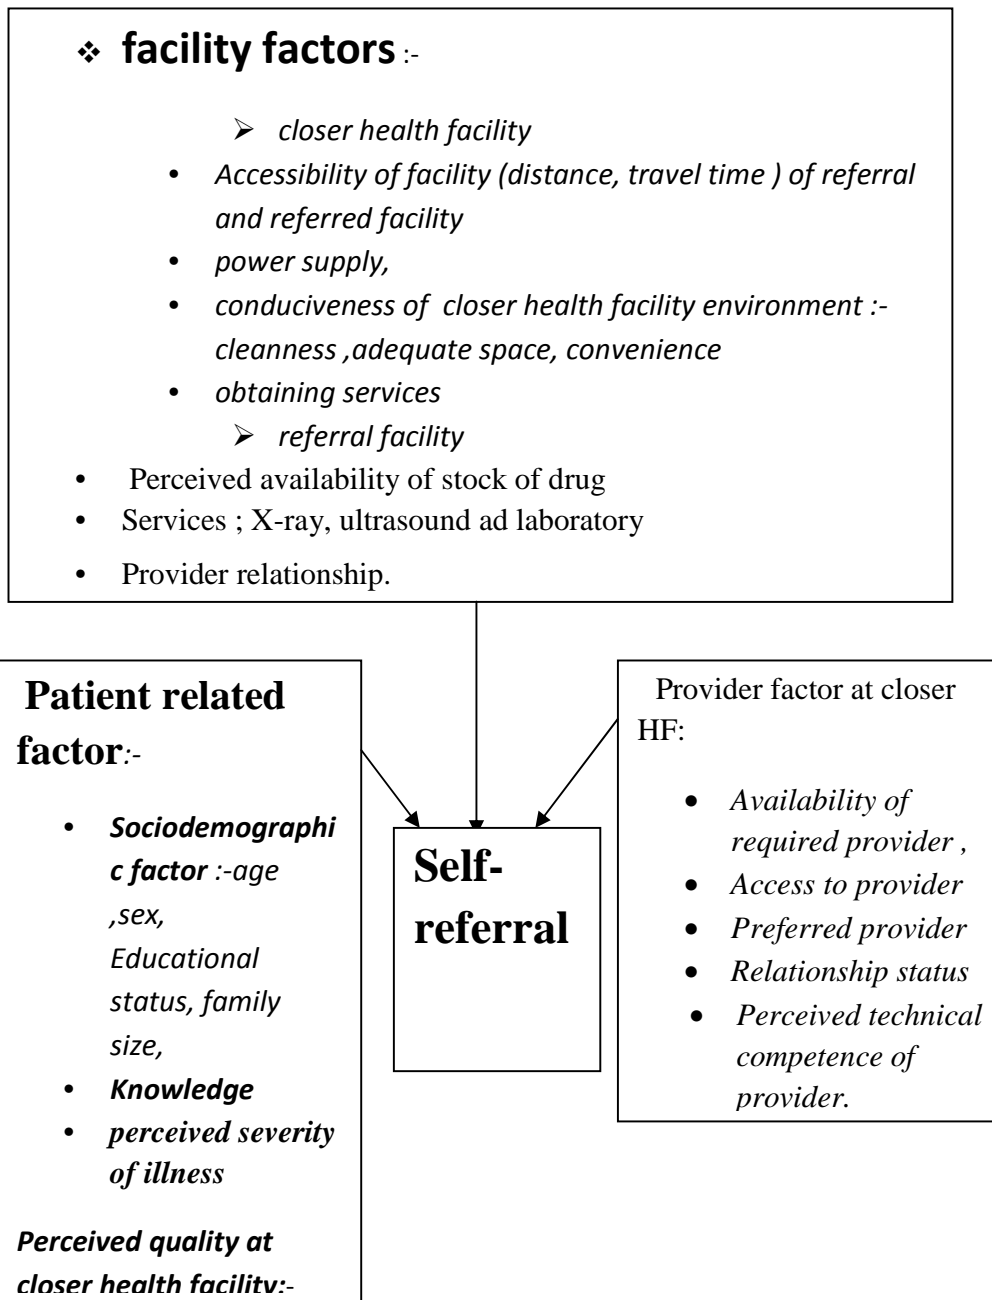

Figure 1: Conceptual framework for determinants of self-referral adopted by principal Investigator after revising related literatures, April 2014

### **1.3 Significance of the study**

High numbers of self-referrals amongst population highlight the beneficiaries' own perception of risk, and the under-utilization of the lower level or over-utilization of higher-level hospitals may be seen to help ease patients' anxiety (20).

Despite the presence of referral system, many patients bypass lower level and go for a higher level of health care. This study will identify those determinant factors for self-referral of patients to higher level of care with minor health problems, which could have been managed at lower levels of health care facilities. This study will provide valuable information for health care managers' to realize the determinants for self-referral and knowing factors associated with patient self-referral will be useful to provide evidence in terms of improving the quality of care at primary level health care and the findings of this study will also serve as a baseline data for future studies.

## **Chapter 2: Literature Review**

### **2.1 Patient expectation vs referral**

A Study conducted in Scotland shows on the first contact with a healthcare practitioner, particularly if that contact is with a GP, 90% of patient needs can be met. If the initial problem cannot be managed, the decision will be made to refer the patient to a specialist or hospital outpatient department (21).

The referral system offers one strategy for making the best use of hospitals and tertiary healthcare services, but all patients should be seen first by a primary healthcare physician who decides whether a referral is necessary. In other words, access to hospital care should be through primary health care centers, except for emergency cases where patients may access the hospital directly via the hospital's emergency department. This avoids system inefficiencies such as disadvantaged groups suffering from a lack of specialist care due to specialist doctors being overwhelmed by inappropriate self-referrals (22).

### **2.2 Perceived quality of health care vs self referral**

The fact that quality perceptions have a strong influence on one's inclination to avail health services is beyond dispute. Thus, expanding access or holding the line on costs is not enough if one's confidence in the quality of health care services is low. Perceptions of poor quality of health care may, in fact, dissuade patients from using the available services because health concerns are among the most salient of human concerns. If the system cannot be trusted to guarantee a threshold level of quality, it will remain underutilized, be bypassed, used only for minor ailments, or used as a measure of last resort (23).

Studies done in India shows that there are varying reasons why patients seek care directly from hospitals. 55.7% of caretakers sought care directly at the referral facility because they perceived that the referral facility provided better quality services. Atkinson and colleagues found differing results in urban Zambia, where people sought care at hospital facilities, not for perceived improved quality services, but because they thought they were less costly and better stocked with drugs ( 24). In Tanzania patients bypassing nearby health centers to seek health care at distant hospitals and private facilities show evidences of their understanding of various measures of quality at the facilities that they visit and bypass (25). In addition to high cost and poor access, dissatisfaction with the health

system (especially shortage of medicines in facilities) affects health-seeking behavior and continues to make accessing health services unpractical or impossible for much of the rural population in Kenya (26).

Similarly perceived quality accessibility and price were among the most important factors affecting utilization of health facilities in Ethiopia (27-29). On the other hand, there are also reports suggesting that usage of health facilities is sensitive not just to the distance to the nearest facility, rather to the quality of health care provided (30,31).

### **2.3 Provider related factors vs self referral**

In a telephone survey conducted in the mid western plan, among patients who recently self-referred responded why they chose to bypass their primary care physicians. Most commonly, patients (37.5%) reported that they preferred to directly access a specialist to save time or to choose their own specialist. The second most common reason (27.8%) was that patients experienced relationship problems with their primary care physicians. Such problems most commonly occurred because physicians refused to make a requested referral. Some patients (22.9%) responded that an established relationship with a particular specialist was the reason for self-referral. Just 3.5% of patients self-referred because they did not have a primary care physician (32).

Leonard et al (2002) examined bypassing in 90 villages in Tanzania studies shows that patients seek higher quality providers with better staff and basic supplies and tend to understand the importance of these factors for their illness conditions (33).

Study done in Pakistan on evaluating of effectiveness of patient referral system shows the reasons why patients by passed the first level care facilities (FLCF), went to higher health care level, 20% claimed unavailability of physician at the FLCF (34).

### **2.4 Educational status and self-referral**

Study conducted in Nigeria shows patients' educational status had no influence on whether they were referred or not. Therefore, both the educated and uneducated bypass the lower levels of health care to obtain health care at the Teaching Hospital. Some reasons for this include; the fact that people have little confidence in the care they would receive outside the hospital and lack of well-designed referral system with defined procedures, management support and appropriate forms (6, 35).

## **2.5 Facility factor vs self-referral**

By examining characteristics of bypassed facilities, it is possible to provide information of relevance to policy-makers. An individual going to a facility that is further away is indicating that the further away facility is preferable to closer ones. Are these facilities, which, in spite of their proximity to ill individuals, are not open long enough hours, are too crowded, and are under-staffed, charge fees for care that are too high, or are missing vital equipment and medical supplies? Ministry of Health officials and other policy-makers in developing countries are intensely interested in the reasons that an ill person, especially a poor one or one severely ill and in need of care, would bypass a government health facility, not only to go further to health facility but often also to pay for the care rather than receive it free of charge at the closer facility (36).

Although the physical proximity to health facilities was viewed as satisfactory, the utilization pattern raised several concerns. This phenomenon was common to all types of healthcare facilities. Hence, it was evident that providing healthcare facilities closer to households alone would not improve access to such facilities unless the issue of bypassing is adequately addressed. Resources spent on maintaining a widely distributed provider network is unlikely to be justified in the long run if some facilities are over utilized while many others are underutilized. The phenomenon of bypassing a closer facility to attend a more distance one could further increase the demand on certain facilities, thus leading to rationing of services. Apart from rationing of services, deterioration in quality of services could follow (37).

In most Sub-Saharan African countries, weak competition in the health sector creates a situation where the population is often faced with local primary health care monopolies. Despite this weak competition, some individuals choose to be treated in health centers further away from their homes, and thus incur greater time and transport costs in order to obtain services they perceive as being better adapted to their needs. Study conducted in Sri Lanka shows, in the rural district close to 2/3 of individuals seeking treatment-bypassed facilities. In particular, the more severely ill patients are more likely to bypass health facilities (38).

In African studies, the profile and sophistication of referral centers may result in patients bypassing lower levels of care and present themselves to higher levels irrespective of the triviality or seriousness of their medical complaint. Up to 82% of maternity hospital users in African studies have been found to be self-referrals (13). Education seems to play a role but even those with higher education have a poor knowledge of referral channels in the health care system. Many patients do not necessarily know the difference between the different levels of care. Patients may also lack confidence in the quality of care available at primary health care level and may perceive hospitals as providing better care, with doctors deemed more capable than nurses or midwives at managing their medical problems efficiently and effectively. High numbers of self-referrals amongst the obstetric population highlight women's own perception of risk, and the inappropriate use or over-utilization of higher-level hospitals may be seen to help ease patients' anxiety (20).

## **2.6 Severity of illness and bypassing**

The study conducted in Sri Lanka shows the relationship between severities of illness and bypassing facilities seems likely to be tied simply to the fact that more severely ill individuals are more willing to travel greater distances than mildly ill individuals do in order to get what they perceive as quality care. As a result, they are also more likely to bypass facilities. Obviously, the geographic structure of the health system helps to show that individuals will travel further if ill to get to the high-level facility. If the geographic layout were such that everyone lived nearer the highest-level facility, we would not be able to identify the fact that people who are severely ill travel further to get to this type of care. When people are very ill, they tend to go directly to the high-level facility. Having lower level facilities nearby is not likely to affect this behavior for many patients. On the other hand, the less severely ill seem to be more willing to save travel time by using perceived lower quality care. When service quality is equal, users will frequent the nearby health facility, but when quality of the services offered is appreciably lower, even care provided free of money cost and in close proximity will not be sufficient to attract many of the potential users. Significant numbers of the poor and the rich, the severely ill and the less severely ill simply will not patronize health providers who do not provide quality above some level of perceived necessary quality (34).

A study done on evaluating of effectiveness of patient referral system in Pakistan in 2001 tried to assess the reasons why patients by passed the first level care facilities (FLCF), went to higher health care level , 11% said that since they were too ill to be taken to the FLCF it has no use to go there and lose time. About 9% gave a variety of other responses. Even for minor illnesses, 14% of the respondents still preferred to directly visit a tertiary care hospital (36).

## **Chapter 3: Objectives of the study**

### **3.1 General objective**

Assess the magnitude and determinants of self-referral of patients at Nekemte general hospital.

### **3.2 Specific objectives**

1. To assess the magnitude of self-referral of patients.
2. To identify determinants facilitating self-referral of patients.

## **Chapter 4: Methods and materials**

### **4.1 Study area and period**

This study was conducted from April 16 - 30, 2014 at Nekemte general public hospital located in Nekemte town administration, East wollega zone, western Ethiopia. The zone is located 330 km west of the capital city Addis Ababa. It comprises 17 woredas, 1 town administration, and according to 2007-population census the total population size of the zone is 1,580,468 comprising of 49.2% male and 50.8% female.

The zone has one public general hospital, which is Nekemte general hospital, located in Nekemte town, one functional primary hospital and two under construction. There are 58 health centers, one tertiary hospital under construction and health service coverage of east wollega zone in 2012/13 was 91%.

Nekemte Hospital serves for about 1.6 million populations and provides health care services seven days per week, the average daily OPD patient flow was about 300 including new, revisit, emergencies and cold cases of both facility referred and self-referred patients by deploying staff of different disciplines at six case teams of OPD service.

### **4.2 Study Design**

Cross sectional facility, based study design was employed.

### **4.3 Population**

#### **4.3.1 Source population:**

All patients who were attending OPD at Nekemte public general Hospital during the study period.

#### **4.3.2 Study population:-**

Sampled patients who were attending OPD service at Nekemte public general Hospital.

#### **4.3.3 Study unit: -**

Selected patient who were attending service at Nekemte public general Hospital.

## 4.4 Inclusion and exclusion criteria

### 4.4.1 Inclusion criteria

Patient who attends care at OPD of Nekemte general hospital.

### 4.4.2 Exclusion criteria

- Patients with mental health problems.
- Emergency life threatening cases.
- Unable to hear and speak.
- Age less than 15 years

## 4.5 Operational definition

- ❖ **Self-referrals:** - are patients who visit secondary referral hospital without referral slip.
- ❖ **Referred patient:** - is patient with referral slip from lower health facility.
- ❖ **Health care provider:** refers to all physician, health officer and nurses who take history, physical examination and treatment at OPD of closer health facility.
- ❖ **Closer health facility:** is public health facility (health center or primary hospital) with in 10 km distance from place of residence.

## 4.6 Sample size determination and sampling technique

### 4.6.1 Sample size determination

The required sample size was determined by using single population proportion formula considering the following assumptions: since there were no published study on prevalence of self-referral at secondary referral level proportion of 50 % self-referral rate was taken, Margin of error = 5%, and Non-response rate = 10%

The formula for calculating the sample size was,

$$n = \frac{(Z_{\alpha/2})^2 p(1-p)}{d^2} = \frac{(1.96)^2 * .5 * (1-.5)}{(0.05)^2} = 384$$

With the above assumptions, the sample size was calculated and the overall sample size was found to be =384 +39 (10% non-response rate) = 423 (users).

### 4.6.2 Sampling technique: -

Systematic sampling technique was employed

Based on record review of monthly patient flow at Nekemte General Hospital, during the same month last year, was found to be 6850 excluding patients with emergency case. Taking in to account the average monthly patient flow and two weeks study period, the sampling interval was calculated, using the following formula:-

$$K=N/n \text{ where } N=3425, n=423 \quad K=3425/423 = 8.1$$

The sampling interval was found to be 8 and using lottery method random number ranging from 1-8 (first sample) was selected which was 3 and every 8<sup>th</sup> (3rd, 11th, 19<sup>th</sup> .....) patients were selected from registration at record office.

## **4.7 Measurement**

### **4.7.1 Data collection instrument: -**

Pre-tested structured questionnaires for face-to-face interview were used to collect data. The questionnaires contain variables related to socio-demographic, knowledge of patients, patients' experience on service, patients' perception on provider related factors at closer health facility and perceived severity of illness were prepared in English and translated to Afaan Oromo language.

### **4.7.2 Data collection procedure**

Data on magnitude and determinants of patient for self-referral was collected using a structured questionnaire prepared for this purpose separately for each patient. One person was assigned at record office to trace sampled patients and they were traced by using serial number from registration book at record office ,based on the sampling interval (K=8) calculated . Data collectors who were assigned at each of six case team room, collected information from the person assigned at record office to trace list of participants, regarding to which case team room that the study participants were assigned. Structured questionnaire for face-to-face interview, which was prepared in English version, was translated to local language and were distributed to data collectors and the data collectors at each case team collected data separately from each study participants by using interview method.

#### 4.7.2 Study Variables

##### Dependent variable

- ❖ Self-referral to secondary referral level.

##### Independent Variable

- ❖ Patient related factor:-

- Sociodemographic factor :-age ,sex, educational status, family income , family size , Place of residence (urban /rural)
- Knowledge
- perceived severity of illness
- Perceived quality at health facility:-confidence of pt on service of closer facility, recommend the service to others

- ❖ Closer health facility factors :-

- Accessibility:- distance ,travel time,
- Availability of provider, power supply,
- comfort :-cleanness ,adequate space, convenience
- obtaining services; laboratory ,drug supply

- ❖ referral facility factors

- Availability of stock of drug
- Services ; X-ray, ultrasound and laboratory
- Provider relationship

- ❖ Provider factor at closer health facility:

- Availability of required provider ,
- Access to provider,
- Preferred provider,
- Relationship status,
- Perceived technical competence of provider,
- Verbal referral.

#### **4.8 Data processing & analysis**

After data collection, each questionnaire was checked for completeness and code was given during data collection. Data were entered and analyzed using SPSS version 20-computer software. Descriptive statistics like frequency tables, graphs and descriptive summaries were used to describe the result. Bivariate logistic regression was performed to include all potential variables. Variables with p-value less than 0.25 with bivariate logistic regression were entered to multivariate logistic regression. p-value less than 0.05 with multivariate logistic regression was used as cut off point for presence of statistical significance.

While fitting the different groups of variables in different models, variables that show significant association with the outcome variable were reported at every step, model one to the final model. Finally, all groups of explanatory variables were fitted to a single model and variables with p-value <0.05 was reported as factors associated with self-referral factors with both p-values and adjusted odds ratios and 95% CI.

#### **4.9 Data quality control**

To achieve a good data quality:

Data collectors (diploma nurses) were selected based on ability to speak the local language and previous experience of data collection. Training was provided to data collectors and supervisor for one day about the objective and process of data collection. The questionnaire was translated to local language, which is Afaan Oromo. Vague points and other problems encountered about the questionnaire were given explanations and clarifications. Closer supervision was undertaken during data collection. The supervisor and the principal investigator crosschecked every questionnaire daily for their completeness. Problems faced were discussed over night with data collectors and the supervisors. Trained data collectors outside study area at Gimbi hospital did pre-testing on 10% of sample in order to prevent information contamination. Ambiguous questions and repetitive ideas were corrected. Additional response categories were also added based on the pretest findings.

#### **4.10 Ethical consideration**

The study obtained ethical clearance from ethical committee of Jimma University, college of public health and medical science. Permission paper obtained from Nekemte General Hospital. Similarly after clear discussion about the actual study or explaining of purpose of the study, verbal informed consent obtained from each study participants while the study subjects right to refuse was respected. Identification of study participants by name was avoided on the data collection instrument to assure the confidentiality of the information obtained.

#### **4.11. Dissemination plan**

Based on results and approval by Jimma University, recommendation will be given to- Nekemte general hospital, East wollega zonal health department, Oromiya Health Bureau and MOH.

## 5. Results

Among the total 423, 422 responded to the interview making the response rate 99.8% from which 346(82%) were self-referred patients. They visited Nekemte General Hospital without referral paper. The selected variables of Sociodemographic factors of the study participants were displayed in table 1. Among total respondents 218(51.7%) were female. The median age of study subjects was 32 years and age ranges from 17-84 years. Majority of respondents' age lie between 25-34 and 35-44 years of age, which accounts for 37% and 30% respectively. Three hundred four (80.6%) were married, 179 (42.4%) were farmers followed and 109 (25.8%) of respondents were at level of 9-12 grade.

Table 2. Shows the patients' experience at the closer health facility of the study subjects. From total respondents, 309(73.9%) said, the type of provider they want were not available at the closer health facility. Three hundred seventy three (88.4%) of total respondents said they had no access to the type of provider they want at the closer health facility. Majority of respondents 370(87.7%) preferred GP provider to be available at closer health facility. Three hundred twenty three (76.5%) of respondents said that providers at closer health facility did not explain in the way they understand. In addition, 326 (77.3%) of respondents said providers at closer health facility did not provide full information about their health problem.

A total of 368 respondents visited closer health facility for their current health problem, 292(79.3%) were self-referred. Two hundred sixty one (70.9%) perceived that provider at the closer health facility had no experience with medical problem of patients. Three hundred twelve (84.8%) respondents out of those who had history of visit at closer health facility for their current health problem, perceived that providers at closer health facility did not explained them well about their health problems. Regarding perceived technical competence 307(83.4%) of respondents perceived that providers at closer health facility did not examine them thoroughly (Table 3).

Table 6 shows knowledge of patients on service at closer health facility and referral system; from total respondents 274(65%) responded that they did not know that, either health center or primary hospital was the first referral level. Considering knowledge of patients on type of available laboratory service at closer health facility, from total respondents 273(64.7%) responded that, they did not know. With knowledge on availability of type of provider at closer health facility 323(76.5%) responded that they did not know it and 350(82.9%) of respondents responded that they were not provided

any information on referral system by any health worker from which 294 of them accounts for 85% of self referred patients.

Table 9. Shows from Sociodemographic factors sex and educational status were significantly associated with self-referral at AOR and 95% CI [.494 (.280, .870)] and [2.68, (1.06, 6.74)] respectively. These imply that, females were 50.6% less likely to self refer themselves to Nekemte General Hospital as compared with males. Patients with educational status of grade 9-12 were about 2.68 times more likely to self refer themselves as compared with patients with twelve complete and above.

Regarding patients' knowledge factor for self referral (see table 10) , knowing the closer health facility as first referral level and the obtaining of information on referral system from health worker were significantly associated with self referral to secondary hospital

at AOR (0.24 and 0.65) and 95% CI [(0.164,0.317) and (0.467,0.791)] respectively. The study showed that patients who knew closer health facility as the first referral level were 76% less likely to self refer themselves to Nekemte General Hospital as compared with those who did not know it. Patients who obtained information on referral system from any health worker were 35% less likely to self refer themselves to Nekemte General Hospital than who did not obtained the information from any health worker .

PSI- perceived severity of illness

As shown in table 11 below, obtaining laboratory test service at closer health facility was found to be significantly associated with self-referral status at AOR and 95% CI

1.64(1.37,3.49). With the reference group who obtained all of laboratory test service , those who obtained none of laboratory test at closer health facility were 1.64 times more likely to self refer themselves. Also obtaining prescribed drugs at closer health facility was found to significantly associated with self-referral. Patients who obtained some and none of the prescribed drugs self referred themselves 1.35 and 2.38 times more likely respectively as compared with respondents obtained all of the prescribed drugs( AOR and 95% CI = 1.35(1.08,3.44) and 2.38(2.19,3.77) respectively..

## **6. Discussion**

The magnitude of self-referral at Nekemte General Hospital was 82% of total respondents. But according to health care delivery structure primary level health care facilities are supposed to be the first contact for patients for their health problem from where they may be referred to either secondary or tertiary hospitals. However the finding of magnitude of self referral was lower than previous findings in Nigeria showed, the self-referral rate was 93% and only 7 % of all the new patients that attended the University of Ilorin Teaching Hospital , went through the referral system(1). This difference could be attributed to the difference in the study population and design.

Among Sociodemographic characteristics, only Sex and educational status of the respondents were found associated with self-referral. It showed females were less likely to self refer themselves to NGH as compared with males and patients with educational status of grade 9-12 were more likely to self refer themselves to NGH when compared to educational status of twelve complete and above. However, study in Nigeria showed that patients' educational status had no influence on whether they were referred or not. Therefore, both the educated and uneducated bypass the lower levels of health care to obtain health care at the Teaching Hospital (13).

This study showed obtaining laboratory service and prescribed drugs at the CHF were important factors to utilize them. Those who obtained none of laboratory test service referred themselves more likely than those who obtained all of the laboratory test service during their visit for their current health problem at closer health facility. Similarly study done in Tanzania shows lack of diagnostic facilities at PHC facilities was the main reason given for bypassing them (40).

At the same time 38% and 36% of self-referred patients, obtained none and some of the prescribed drugs at closer health facility respectively and they referred themselves more likely than those who obtained all of prescribed drug at closer health facility. Consistently study in Tanzanian shows lack of drugs was among common reasons given for bypassing lower facilities (40). Additionally it is supported by study conducted in Kenya, which showed that dissatisfaction with the health system (especially shortage of medicines in facilities) affects health-seeking behavior and continues to make accessing health services unpractical or impossible for much of the rural population (15).

The health centers are supposed to be the point of first contact of patients. Patients are then referred from here to other levels of health care. However, 65% of total respondents did not know that health center or primary hospital is the first contact of patients. It is obvious that information on referral system is important but majority of respondents did not get any information on the referral system of health care delivery system from any health care provider.

Illness perception of patient is important in health seeking behavior. This study showed that patients who perceived that their illness was severe, referred themselves more likely than those who perceived mild. This is supported by study conducted in Sri Lanka, which showed the relationship between severities of illness, and bypassing facilities seems likely to be tied simply to the fact that more severely ill individuals are more willing to travel greater distances than mildly ill individuals do in order to get what they perceive as quality care. As a result, they are also more likely to bypass facilities (36).

The limitation of this study includes Recall bias, social desirability bias, absence of complementation with qualitative data.

## **7. Conclusion**

The magnitude of self-referral to Nekemte General Hospital was found high as comparing with the standard health care delivery structure of referral system, that primary level health care facilities are supposed to be the first contact of patients for their health problem, from where they may be referred by provider to either secondary referral level ie General Hospital or tertiary hospitals.

Based on this study the main reasons why patients self referred themselves to secondary hospital:-

- Patient related predictors like perceived severity of illness, educational status and sex were identified for self-referral.
- Service at closer health facility factors; obtaining laboratory test service and prescribed drugs at closer health facility were associated with self-referral. Lack of drug supply and inadequate laboratory service evidenced by most of patients obtained some or none of prescribed drugs and none of laboratory test service for them were associated with self-referral.
- Patients' knowledge related predictors were identified for self referral that, majority of them were not provided any information on referral system by health workers and most of patients do not know closer health facility is the first contact of patients for their health problem.

## **8. Recommendation**

Based on the study findings and the above conclusions the following recommendations were forwarded:

- MOH and ORHB should ensure primary level health care particularly health centers with adequate drug supply and laboratory services are essential in building confidence of care at primary level health care.
- Health workers should take measures to aware patients on referral system.
- East wollega zonal health department should conduct research on the impact of self-referral on patients.
- Nekemte General Hospital managers should conduct research on impact of self-referral on the hospital service.

## Questionnaire English version

JIMMA UNIVERSITY COLLEGE OF PUBLIC HEALTH AND MEDICAL SCIENCES

Informed Consent number\_\_\_\_\_

Dear Sir/madam;

I am Master's Degree students from Jimma University. As part of my academic requirements, I am expected to conduct study on determinant factor for self-referral to Nekemte hospital, east wollega, Ethiopia, 2014.

Thus, this interview is prepared for this purpose to get appropriate information on magnitude and determinants of self-referral of patient at Nekemte general hospital, Nekemte. The information that I will obtain using this interview will be used only for research purpose and I need to assure you that confidentiality is my main quality. The study has no risk to you and your family members except mild time consuming. Therefore, I politely request your cooperation to participate in this interview. You do have the right not to respond at all or to withdraw in the meantime, but your input has great value for the success of my objective.

Thank you for your cooperation!!!

Do you agree to participate in this study? Yes, ----- No-----, thank you!
