## **Abstract**

**Background:** Child nutritional status is an essential component of a country's overall human development. It continues to be widespread in a population of more than 200 million children under five (one in three children) in developing countries. To improve the nutritional status and living conditions in communities, it is necessary to determine the nature, magnitude and cause of malnutrition. This is a reason why this study focused to study the prevalence of malnutrition and associated factors in Bule Hora, Borena zone.

**Objective:** To assess the magnitude and factors associated with nutritional status in children under five years age in Bule Hora Woreda, Borena Zone.

**Methodology:** A community-based cross-sectional quantitative study design was used to assess the magnitude and factors associated with malnutrition in children less than five years of age. A structured questionnaire was used to collect data from 796 children paired with their mothers or caregivers. Bivariate and multivariate logistic regression analyses were conducted to identify determinants of nutritional status. Degree of association between dependent and independent variables was assessed using OR and 95% CI. Statistical association was declared as p-value less than 0.05.

**Result: Result:** The result of the study indicated that 47.6% of the children were stunted, 29.2% were underweight, and 13.4 % wasted. Prevalence of severe stunting, underweight and wasting were 20.2%, 6% and 3.9% respectively. Presence of diarrhea, being male by sex, uneducated fathers and total number of children ever born to a mother were significantly associated with underweight. Presence of diarrhea, being male by sex, Pre-lacteal feeding and not using family planning methods were significantly associated with stunting and presence of diarrhea, age at which additional food given and not using family planning were predictors of wasting.

**Conclusion:** As the prevalence of malnutrition among the children was found high, it is recommended that intervention should focus on prevention and control of diarrheal disease through improving access to safe and adequate water supply, immunization, housing, sanitation and hygiene practices and on improving promotion of nutrition education and utilization of family planning.

**Key words:** *nutritional status, under five, stunting, wasting and underweight.*

## **Acknowledgement**

My heart feels great thanks to my advisors Dr. Mekitie Wondafrash and Mr. Mohammed Taha for their timely comment, advice and suggestion to do this thesis.

Also I would like to express my thanks to Jimma University College of public health and medical sciences for giving me the chance to conduct this study.

My thanks also extends to those all who cooperated with me in doing my thesis; The Bule Hora Woreda Health Office staffs, Bule Hora Woreda Health Centers staffs for their help in my research activities while on data collection.

I wish to express my gratitude and deep respects to the Bule Hora Woreda kebele administrators, study participants and community health workers who participated in the study, particularly to those who were directly involved in the study and to data collectors.

Finally I would also like to acknowledge all staff members of the Epidemiology department for all their contribution to my thesis.

WHO – World Health Organization

W/A – weight for age

W/H –weight for height

## **Chapter one - Introduction**

### **1.1 Background**

Malnutrition is the condition that results from taking an unbalanced diet in which certain nutrients are lacking, in excess (too high an intake), or in the wrong proportions. A number of different nutrition disorders may arise, depending on which nutrients are under or overabundant in the diet. In most of the world, malnutrition is present in the form of under nutrition, which is caused by a diet lacking, inadequate calories and protein (1).

Child nutritional status is an essential component of a country's overall human development. There is a growing consensus that poor nutritional status during childhood (and in utero) can have long lasting scarring consequences into adulthood, both in terms of health and mortality, and in terms of other measures of human capital such as schooling and productivity(2). Adequate nutrition is essential in early childhood to ensure healthy growth, proper organ formation and function, a strong immune system, and neurological and cognitive development. Economic growth and human development require well-nourished populations who can learn new skills, think critically and contribute to their communities. Child malnutrition impacts cognitive function and contributes to poverty through impeding individuals' ability to lead productive lives (3, 4).

Malnutrition has three commonly used comprehensive types named stunting, wasting and underweight measures by height for age, weight for height and weight for age indexes respectively. Stunting or growth retardation or chronic protein energy malnutrition (PEM) is deficiency for calories and protein available to the body tissues and it is inadequate intake of food over a long period of time, or persistent and recurrent ill-health (5). Wasting is an indicator of acute malnutrition and usually the result of recent food insecurity, infection or acute illness. Measurement of wasting is often used to assess the severity of an emergency situation, with severe wasting being highly linked with the death of a child. The third type of under five years malnutrition is underweight, an indicator of both acute and chronic malnutrition. It is the indicator used to monitor the Millennium Development Goal (MDG) of ending hunger, and targets of halving the prevalence of underweight children and adults by 2015(6, 7).

## **1.2. Statement of the problem**

Many countries remain far from reaching the first millennium development goal (MDG) and much of the progress made has been eroded by the recent global food price and economic crisis. Progress in reducing childhood malnutrition in developing countries has been slow but more than half of these countries are not on track to achieve the Millennium Development Goal of halving the share of children who are malnourished (low weight for age) by 2015(8-10).

Child malnutrition, an indicator of both the level of food insecurity, care and health in a community and of the nutrition status of future adults (because of malnutrition's intergenerational consequences), continues to be widespread in a population of more than 200 million children under five (one in three children) in developing countries. Twenty-four countries bear 80 percent of the developing world's burden of under nutrition as measured by stunting (an indicator of chronic hunger). In Africa and Asia, stunting rates of under-fives are particularly high, at 40 per cent and 36 per cent respectively. More than 90 per cent of the developing world's stunted children live in Africa and Asia (11).

Reducing malnutrition among children under the age of five remains a huge challenge in developing countries of the World. An estimated 230 million under-five children are believed to be chronically malnourished in developing countries. Similarly, about 54% of deaths among children of this age group are believed to be associated with malnutrition in developing countries. In Sub-Saharan Africa, 41% of under-five children are malnourished and deaths from malnutrition are increasing on daily basis in the region (12).

In Ethiopia, protein energy malnutrition (PEM) is currently the most widespread and serious health problem of children and their mother's .Malnutrition is the underlying cause of 57% of child deaths in the country, with some of the highest rates of stunting and underweight in the world. Without increased efforts to improve the nutrition status of vulnerable groups such as mothers and children under five years old, Ethiopia risks falling short of reaching the Millennium Development Goals (MDGs) of halving underweight and reducing child mortality by two-thirds by 2015(13).

As of EDHS 2011 the under-five mortality rate was 88 per 1000, stunting underweight prevalence was 58%, 51%,44.4% and, 41% 33%, 28.7% according to 2000, 2005 and 2011 EDHS respectively. These rates have decreased quite a bit in the past 3 decade, most notably with mortality almost halving. However, Ethiopia still needs a concerted effort to accelerate reductions in under five years age malnutrition (14).

Underweight is reflected by wasting, stunting, or a combination of the two, and therefore MDG1 can be achieved by decreasing the prevalence of either or both (15). In Ethiopia, stunting prevalence increases rapidly after six months of age through two years , highlighting the need for more resources devoted to preventing under nutrition during the critical window from conception to two years of age (also known as the first 1000 days), after which it is almost impossible to recover from the developmental deficits(16) .

Various studies conducted on child nutritional status has given an important insight into the factors influencing child nutritional status of preschool children in different parts of the country. These studies have shown that factors such as household economic status, education of mother, employment status of mother, employment status of father, source of water and availability of toilet facility, child morbidity, age of child, birth order, birth interval of child and maternal nutritional status have a significant influence on child nutritional status. However, little attention seems to have given to the pastoralist and semi pastoralist areas.

In Bule Hora Woreda a number of cases of malnourished cases come to Bule Hora Hospital and Health Centers of the Woreda for treatment but there is no study conducted in the area to identify the factors associated with under five years malnutrition .To improve the nutritional status and living conditions in communities, it is necessary to determine the nature, magnitude and cause of malnutrition. Broad analysis of causes of malnutrition is required before action. Therefore this study aims to study the prevalence of malnutrition and associated factors in Bule Hora, Borena zone.

## **Chapter Two - Literature Review**

### **2.1 Magnitude of Malnutrition**

Globally, 10.6 million children below 5 years of age die every year. Under-nutrition accounts for about 35% of all deaths among these children and also the number one cause of morbidity for all age groups, accounting for 11% of the disease burden. Stunting, severe wasting and intra-uterine growth retardation are the major contributors to child mortality, accounting for about 2 million deaths of under-fives annually (17). The World Health Organization estimates that about 60% of all deaths, occurring among children aged less than five years in developing countries, could be attributed to malnutrition. PEM continues to be a major health burden in developing countries and the most important risk factor for illnesses and death especially among young children (18).

Maternal and child under nutrition account for 11% of the global burden of disease. Stunting, a chronic slowing of linear and cognitive growth, often results from inadequate access and intake of nutritious food, poor health, and inadequate child and maternal care. This chronic under nutrition affects one out of three children under five years of age in the developing world, with 80 percent of these children residing in just 22 countries(4).

A community-based descriptive cross sectional study conducted in Khartoum to assess the impact of feeding practices on prevalence of under nutrition among 6-59 months old children shows that out of 780 households visited, the prevalence of malnutrition among 6-59 months children in the study were 11.8% for moderate acute malnutrition, while 7.3% were severely wasted. Severe chronic malnutrition was observed in 27.1% while 24% were moderately malnourished, for underweight 13.6% were severely under-weight, while 21.4% were moderate (19).

A cross sectional study conducted by Bloss E. et al on prevalence and predictors of underweight, stunting, and wasting among children aged five and under in western Kenya shows that the prevalence of stunting and wasting were 47% and 7% respectively. The study also revealed that mothers who had no formal education were more likely to have children who were underweight than mothers who had secondary school (20).

Olack B et al (2011) revealed that the prevalence of stunting among children aged 6-59 months was 47%, and the prevalence increased with age through 36-47 months (58%). Severe stunting was found in 23.4% of the children. Stunting peaked (56%) in children aged 36-47 months, and compared to other age-groups, stunting was significantly more likely in children aged 36-47 months. Similar proportions (51.3%) of males were stunted as females (48.7%) (21).

A cross sectional study conducted by Shubhada S. et al on epidemiological study of malnutrition (under nutrition) among under five children in a section of rural area revealed that Out of 329 malnourished children 171 were males and 158 were females. The prevalence of malnutrition was significantly more in 1-3 year age group and the authors suggested that improper weaning, recurrent infections make this age group more vulnerable(22).

According to EDHS 2011, 44 percent of children under age five are stunted, and 21 percent of children are severely stunted. In general, the prevalence of stunting increases as the age of a child increases, with the highest prevalence of chronic malnutrition found in children age 24-35 months (57 percent) and lowest in children under age six months (10 percent). Male children are slightly more likely to be stunted than female children (46 percent and 43 percent, respectively). With the exception of first order births, there is an inverse relationship between the length of the preceding birth interval and the proportion of children who are stunted. The longer the interval, the less likely it is that the child will be stunted (14).

A study conducted on Magnitude and Factors Associated with Malnutrition of Children under five years of age in rural kebeles of Haramaya shows that malnutrition of children aged birth to 59 months was identified with stunting in 42.2% of the children. A total of 36.6% of the children were underweight and 14.1% were wasted. The study also revealed that, majority (59.4%) of the mothers claimed they fed their child with colostrum immediately after birth and the remaining mothers 40.6% provided the child with pre-lacteal feeding. Children who experienced coughs or diarrhea episodes in the preceding two weeks of the survey days were 26.5 % (23).

## **2.2. Factors contributing to Malnutrition**

Factors contributing to the development of protein-energy-malnutrition (PEM) include cultural and social practices that lead to the exclusion of certain foods due to food taboos, food and dietary fads and migration from rural areas to urban slums (24).

The global conceptual framework developed by UNICEF identifies malnutrition and death in children and women as the result (final outcome) of a long sequence of interconnected events. These events can be classified as components of three major groups of causes: the basic, the underlying, and the immediate determinants of malnutrition. Inadequate dietary intake and disease are considered as the most significant immediate causes of malnutrition of children and women (25).

The underlying causes for inadequate dietary intake and diseases can be numerous. These are context-specific and the most important fall within the three interrelated groupings of insufficient food availability and access, inadequate care for children and mothers, and insufficient health services and inadequate provision of a healthy environment (e.g. clean water and sanitation). Finally, the major basic or structural causes of malnutrition in the hierarchy include economic, technological, political, cultural, and institutional structures and processes, the means of control of physical resources, and the level of human development (25).

Diseases are the main immediate causes of malnutrition. Most deaths of children 6-59 months old are related to malnutrition and infection. Infections play a major role in the etiology of PEM because they result in increased needs and a high energy expenditure, lower appetite, nutrient losses due to vomiting, diarrhea, poor digestion, mal-absorption and the utilization of nutrients and disruption of metabolic equilibrium (24).

Food insecurity was associated with reduced intakes of important nutrients, behavioral and psychological dysfunction as well as poor health in children. Children from food-insecure households were twice likely to have their health status reported as fair/poor compared to those from food-secure households and likely to have been hospitalized than their food-secure counterparts. A study in Bangladesh revealed that children from food-insecure households were found to have a higher rate of morbidity than those from food-secure households(26).It also indicated that children from food-insecure households were introduced to cow milk, fruit juices

and other liquids earlier than recommended and the three types of malnutrition were significantly more prevalent among boys than among girls. The same pattern of early introduction of water, sugar and milk was also observed in Botswana(27).

A study conducted on epidemiological correlates of under-nutrition in under-5 years children in an urban slum of Ludhiana shows that being born with low birth weight appears to carry a higher risk of being underweight in the first five years of life with the prevalence of underweight being observed to be significantly higher in the LBW children. The study also revealed that highest prevalence of underweight, stunting as well as wasting was found in those who were exclusively breastfed greater than 6 months, followed by those who received exclusive breastfeed for less than 4 months and lowest for those who were exclusively breastfed for 4-6 months (28).

Stunting is a cumulative process that can begin in utero and continues to about three years after birth. A study conducted by Teshome Beka and his colleagues on magnitude and determinants of stunting in children under five years of age in food surplus region of Ethiopia identified predictors of stunting. According to this study presence of diarrhea prior to the survey, child received pre-lacteal feeding, being male, child who did not feed colostrum and children who fed less than three times a day were identified explanatory variables which have significant association with stunting(29).

The study conducted in Bangladesh on Predictors of the number of under-five malnourished children in Bangladesh: application of the generalized Poisson regression model by Mohammed I. et al showed that children from father of no education was more likely to be malnourished when compared with children of educated fathers. The study also revealed that total number of children ever born to a woman as a significant factor associated with child malnutrition(30).

According to a survey done by UNICEF and the Institute for Public Health Nutrition in 2004 in Bangladesh, one in four households is food insecure and two million children are affected by malnutrition (between six months and five years). The survey was designed to assess the impact of the food price increases in Bangladesh. Data showed that 58% of households had insufficient

food in the previous year. A link was found between malnutrition and food insecurity, with food insecure households showing a higher percentage of malnourished children (31).

A case control study conducted by Amsalu.S and Tigabu. Z on risk factors for severe acute malnutrition in children under the age of five showed that, in both groups breastfeeding was initiated within the first hour of birth in 73 (71.6%) of the cases, however, prelacteal feeds were given more frequently in the cases 24 (23.5%) than in the controls 12 (13.3). Butter is the most commonly used pre-lacteal feed 19/36(52.8%).The study also revealed that pre-lacteal feeds given, greater than three children ever born to a mother and children from uneducated fathers were positively associated with child malnutrition (32).

Impacts of PEM on the severity of infection was investigated in children with measles, diarrhea, respiratory infections, and malaria, it was found that the morbidity and mortality in patients with infections is worse if they are malnourished (33).

A study done by Bachou et al. (2006) showed that within a group of 315 malnourished children, 119 (38%) were female with a median age of 17 months while only 3% were below the age of six months. They also showed a high prevalence of infections (26%) and bacteremia (18%). The HIV infected children were more likely to have persistent diarrhea than the HIV uninfected malnourished children (34).

The study conducted in Democratic Republic of Congo shows prevalence of stunting was higher among boys compared to girls (46.1 versus 41.7 percent), has an inverse linear association with the age of the child (higher in the age groups ranging from 4 years, followed by 3 years, 2 years, 1 years but lower in the younger age (0 year): 55.1, 49.4, 48.5, 46.5 versus 23.1 percent), higher in rural areas compared with urban areas (48.4 versus 37.2 percent), higher among children born outside the hospital compared with their counterpart born in hospitals (49.1 versus 41.8 percent), linearly associated with maternal education (higher among children from non-educated mother, followed by children from mothers with primary education but lower among children from mothers with secondary or higher education: 49.8, 47.0 versus 35.2 percent )(35).

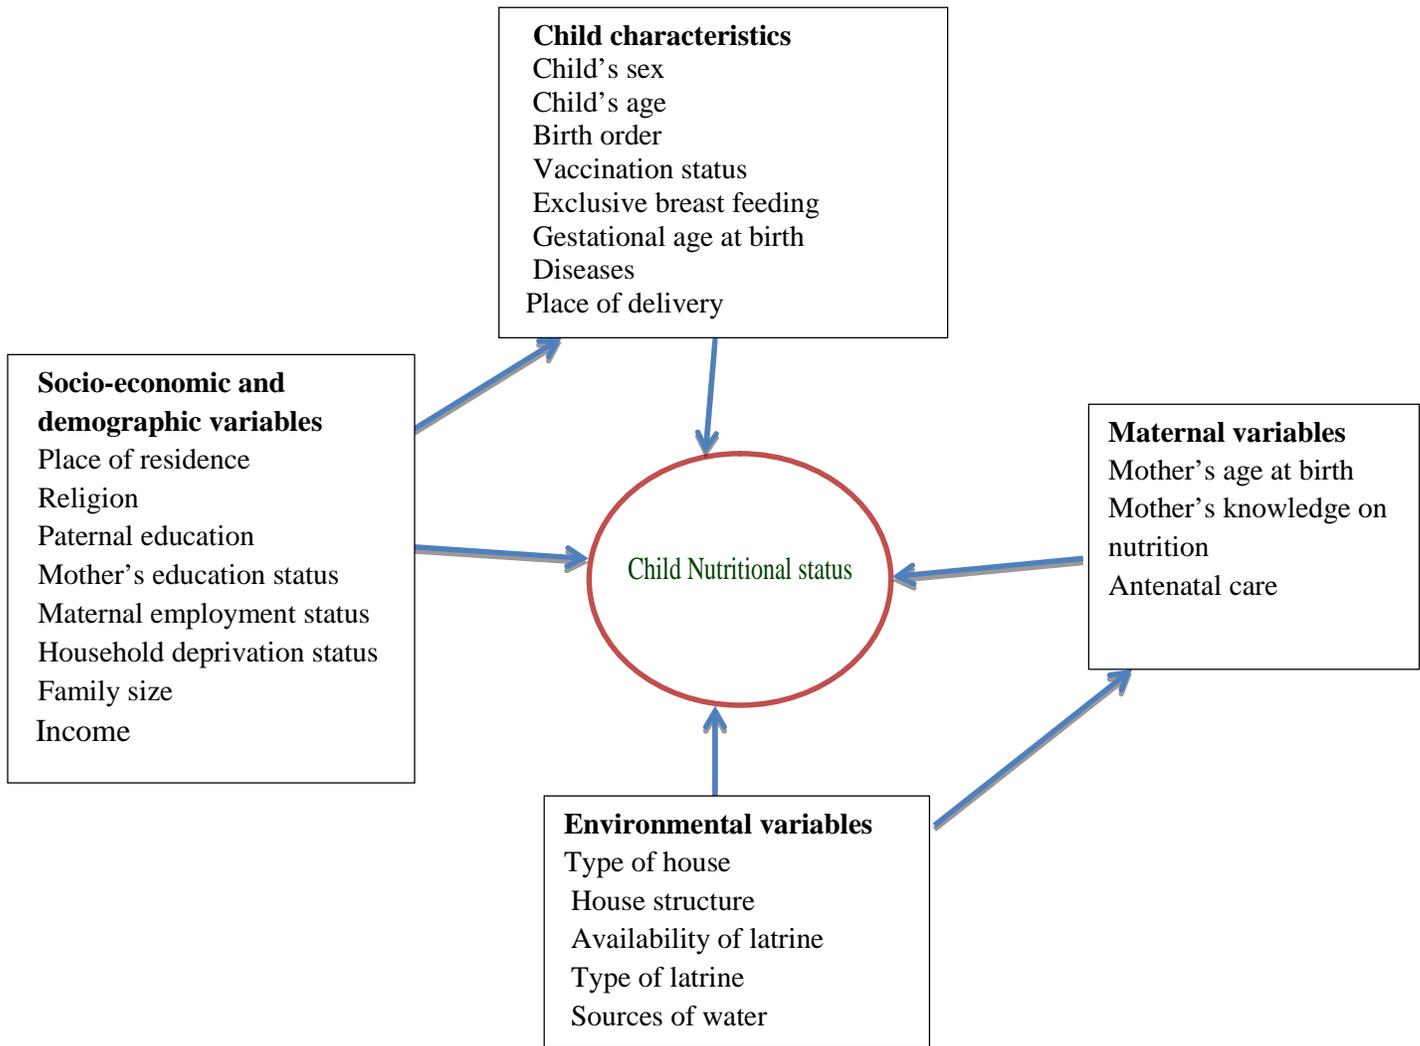

A study conducted on nutritional status and determinants of malnutrition in children under three years of age in Nghean , Vietnam showed that children from a household who use water from unprotected sources are known to be 1.2 times underweight, 0.71 times stunted,0.38 times

wasted when compared with children with households using water from protected sources. And also the study revealed that children from households having family size more than or equal to three are known to be 3.35 times underweight, 2.47 times stunted and 5.46 times wasted when compared with children from households having family size 1-2. A study also revealed that being male, exclusive breast feeding for less than six months, having diarrhea in the last two weeks low birth weight and initiation of breast feed after one hour were identified as variables which are significantly associated with child malnutrition ( for the three types –underweight, wasting and stunting)(36).

A study conducted on socio-economic determinants of severe and moderate stunting among under five children of rural Bangladesh with a sample of 6,058 children 0-59 months showed that among the mothers of the children,39.4% received antenatal care (ANC) services ,10.8% births were delivered at medical facility place and 13.6%births were delivered by skilled delivery assistants(SBA). Additionally, over one-third of the fathers of the children had no formal education, while over one-fourth had primary education, one-fourth had secondary education and 8.9% had higher education. Almost three-fourths of the mothers were not working. For water, 86.0% used piped or tube well water and 14.0% had no sources of safe water for drinking. Of the children, almost one third were the first child, one-fourth were the second child, less than one-fifth were the third child, 11.3% were the fourth child and the rest (13.8%) were the fifth or higher order births of their parents(37).

Unsafe water, poor sanitation and unhygienic conditions claim many lives each year. An estimated 1.2 million children die before the age of 5 from diarrhea. Poor urban areas where insufficient water supply and sanitation coverage combine with overcrowded conditions tend to maximize the possibility of faecal contamination(38). A Case Study from Goundam Cercle, Timbuktu Region found that children whose family had latrine facility at their home shows prevalence of 27.8% of under nutrition, while those families with open air defecation had 40.7% of prevalence of under nutrition(39).

## Conceptual framework of the determinants of malnutrition

**Figure 1. Conceptual framework which shows causes of child malnutrition**

Source: Victora et al, 1997(40).

## **Significance of the study**

Developing countries are facing the universal problem of child malnutrition. Even in many developed countries malnutrition of “under five” children is a threat for health policy makers because of the diversity in child rearing practice and health seeking behaviors. For the last few decades, Ethiopia has spent millions of dollars through different interventions including child immunization, primary health services, parental education and media communication. Almost all of them are direct intervention to the community. As nutritional status can vary by background characteristics, there is a need to investigate underlying variations of these nutritional indicators and determinant factors among regions and localities or residence for proper priority setting and interventions.

The result of this study, which specifies the prevalence of child malnutrition with these various causes and their relative contributions, can serve as reference in priority setting, designing effective nutritional programs to address the problem and its consequences, in monitoring and evaluation of the impacts of programs and for policy responses specifically tailored to the needs of different population groups.

## **Chapter Three – Objectives**

### **3.1. General Objective**

- To assess the magnitude and factors associated with nutritional status in under five years age in Bule Hora Woreda, Borena Zone, Oromia regional state, Southern Ethiopia.

### **3.2. Specific objectives**

- To assess the prevalence of under nutrition in under five years children in Bule Hora Woreda.
- To identify the associating factors of under five years nutritional status in Bule Hora Woreda.

## **Chapter Four - Methods and Materials**

### **4.1 Study Area and Period**

The study was conducted in Bule Hora district from February 25 to March 25, 2013. Bule Hora is one of the Woreda in fourteen Woredas of Borena zone with 48 kebeles (43 rural and 5 town kebeles) with a total population of 317,341 of which 52,044 are under five children. Bule Hora is found at 468 km from Addis Ababa to the South and 100 km from zonal town, Yabello. The Woreda has 1 university, 1 district hospital, 1 teachers training college (TTC), 2 private nursing college, 8 health centers, 27 health posts and 42 private clinics (all types). The Woreda is bordered on the south by the Dawa River which separates it from Arero Woreda, on the southwest by Dugda Dawa Woreda on the west by the Southern Nations, Nationalities and peoples region, on the northeast by Kercha Woreda of Guji zone, and on the east by Odo Shakiso Woreda.

According to 2007 national census, concerning the religion, majority (74.42%) of the inhabitants are Protestant, while 11.24% of the population practiced traditional beliefs, 5.85% are Orthodox, 5.81% are Muslim and 1.4% are Catholic. The four largest ethnic groups are Oromo (70.98%), Gedeo (25.77%), Amhara (1.16%), and Burji (0.87%); all other ethnic groups made up 1.22% of the population. Afan Oromo was spoken as a first language by 72.2%, 25.41% spoke Gedeo and 1.59% spoke Amharic; the remaining 0.8% spoke all other primary languages reported.

**4.2. Study Design:** A community-based cross-sectional quantitative study design was used.

**4.3. Source Population:** The source population was all children less than five years of age in the district of Bule Hora who lived in the study area for at least six months prior to data collection.

**4.4. Study Population:** The study population was children 6-59 months who are residing in the eight randomly selected kebeles in the district of Bule Hora.

#### **Inclusion and exclusion criteria**

- Children 6 to 59 months of age
- Children who resided in the area for six or more months prior to data collection

**4.5. Sample Size and Sampling technique:**The required sample size of the study population was determined by using the single proportion formula:

$$n=Z (\alpha/2)^2 * p (1-p)/d^2.$$

Where,

n= sample size

Z $\alpha/2$ =confidence level (1.96)

P=proportion of under five children affected by malnutrition, 44% (prevalence of stunting, from EDHS 2011, which gives highest sample size)

d=margin of error (5%)

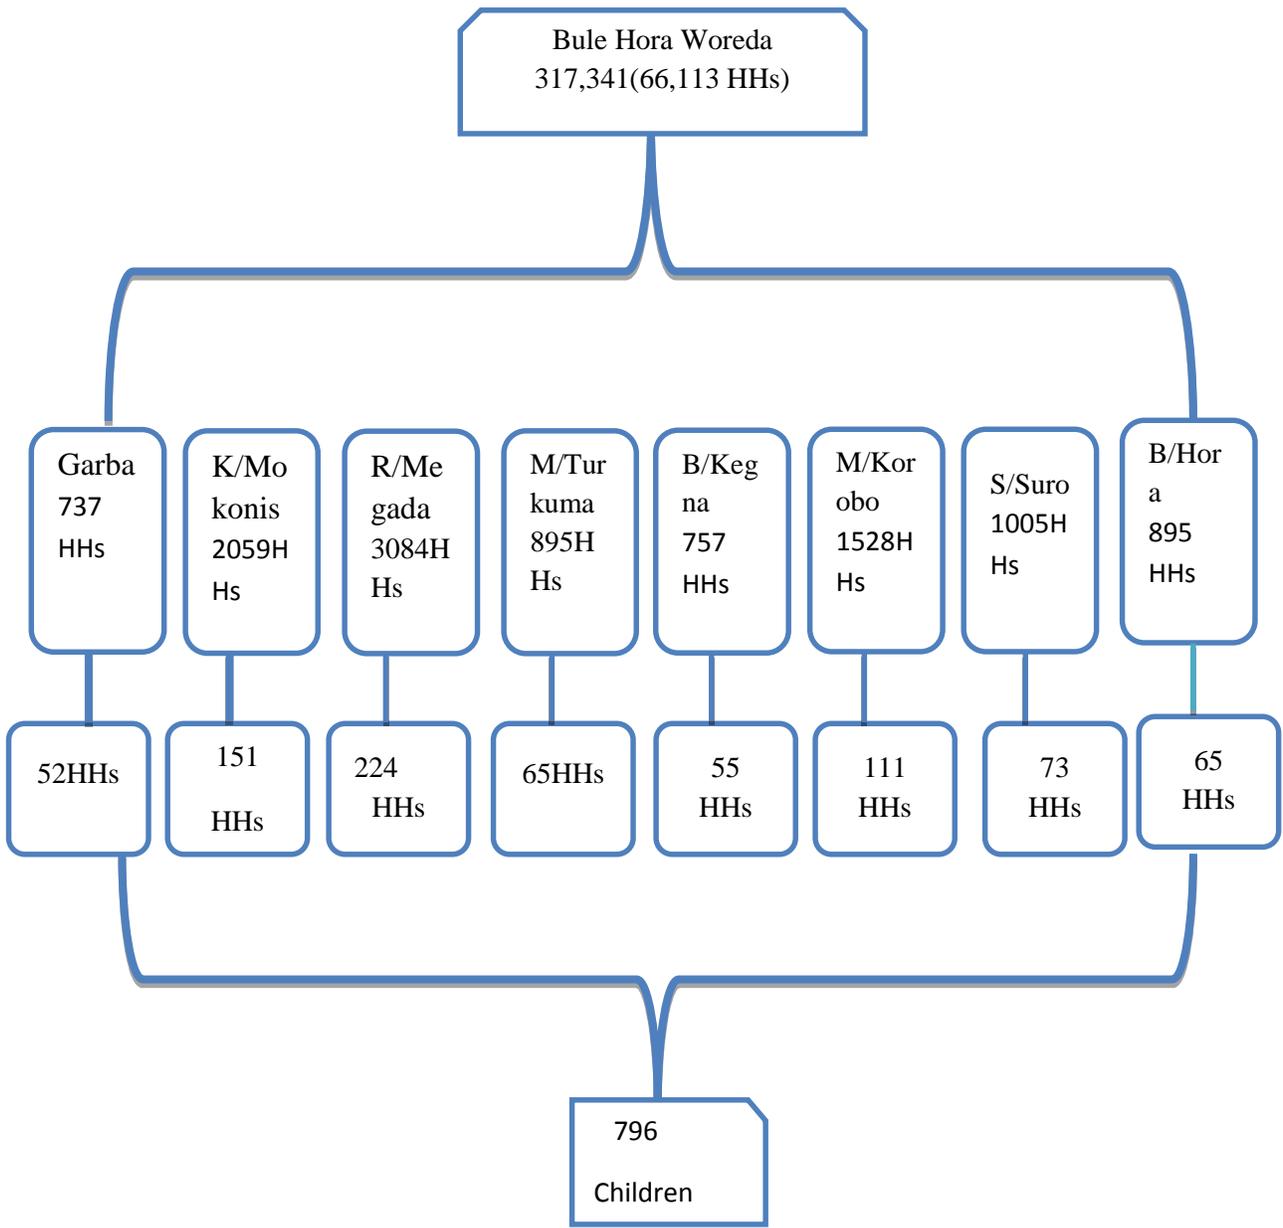

$$n = (1.96)^2 * 0.44(1-0.44) / (0.05)^2.$$

$$n=379$$

The sample size was n=379, by using design effect 2, the sample was 758, and also adding non-response rate of 5%, total sample size was 796. Accordingly, 796 children paired with their mothers/caregivers were selected.

## **Sampling procedure**

A multi-stage random sampling technique was used to select the target population. Out of 48 kebeles eight were selected by using simple random sampling. From these selected kebeles, 13,048 children 6-59 months from 10,960 households were identified by using the registration at health posts and cross-checking these registration with that of community based nutrition registration. In households with more than one children of age between 6-59 months, one child was selected randomly by lottery method. Finally, by proportional allocation of the sample size to each kebele 796 children paired with their mothers or caregivers were selected.

**Figure 2- Schematic representation of Sampling Method, Bule Hora Woreda**

#### **4.6. Data Collection Methods and Instruments**

Data was collected using structured questionnaire and anthropometric measurements. Eight nurses and eight community health workers from each selected kebeles were involved in the data collection. These nurses were recruited from Bule Hora Woreda Health centers those who have taken training on community based nutrition (CBN) and two supervisors were health officers working at Bule Hora health office. Both the interviewers (nurses) and supervisors were trained for two days on objective and methodology of the research, data collection and interviewing approach, anthropometric measurement and data recording.

Weight was measured with minimum clothing and no shoes using a hanging scale and electronic beam balance in kilogram for those less than 24 months and 24-59 months respectively, to the nearest of 0.1 kg. Measurement of length was done in a lying position with wooden board for children of age under two years and measurement of height for children above two years stature was measured in a standing position in centimeters to the nearest of 1cm.

MUAC was measured using non-stretchable tape on left mid upper arm to the nearest 1mm. Edema was assessed by applying medium thumb pressure on upper side of both feet for three seconds. It was diagnosed if a bilateral depression (pitting) remained after the pressure is released.

To identify retrospective morbidity of children, mothers were asked about any occurrence of illness during the past two weeks. Enumerators probe to confirm nature of illness based on operational case definition and also ask to identify occurrence of measles in the past six month. Vaccination status of children was checked by observing immunization card and if not mothers were asked to recall it. BCG vaccination was checked by observing scar on right (also left) arm.

## **4.6.1 Measurement of child nutritional status**

### **4.6.1.1 Height-for-age**

The height-for-age index provides an indicator of linear growth retardation and cumulative growth deficits in children. Children whose height-for-age Z-score is below minus two standard deviations ( $-2$  SD) from the median of the WHO reference population are considered short for their age (stunted), or chronically malnourished. Children who are below minus three standard deviations ( $-3$  SD) are considered severely stunted. Stunting reflects failure to receive adequate nutrition over a long period of time and is affected by recurrent and chronic illness. Height-for-age, therefore, represents the long-term effects of malnutrition in a population and is not sensitive to recent, short term changes in dietary intake.

### **4.6.1.2 Weight for Age**

Weight-for-age is a composite index of height-for-age and weight-for-height. It takes into account both chronic and acute malnutrition. A child can be underweight for his/her age because he or she is stunted, wasted, or both. Weight-for-age is an overall indicator of a population's nutritional health. Children with weight-for-age below minus two standard deviations ( $-2$  SD) are classified as underweight. Children with weight-for-age below minus three standard deviations ( $-3$  SD) are considered severely underweight.

### **4.6.1.3 Weight-for-height**

The weight-for-height index measures body mass in relation to body height or length; it describes current nutritional status. Children with Z-scores below minus two standard deviations ( $-2$  SD) are considered thin (wasted) or acutely malnourished. Wasting represents the failure to receive adequate nutrition in the period immediately preceding the survey and may be the result of inadequate food intake or a recent episode of illness causing loss of weight and the onset of malnutrition. Children with a weight-for-height index below minus three standard deviations ( $-3$  SD) are considered severely wasted.

#### **4.6.1.4 Mid-Upper Arm Circumference (MUAC)**

As that of Z-scores Cut-off points used to classify the severity of malnutrition also can presented by MUAC. In 2009, WHO and UNICEF endorsed the cut-off point of MUAC less than 115 mm/11.5cm as severe acute malnutrition and  $\geq 115\text{mm} \ \&< \ 125\text{mm}$  as moderate acute malnutrition(41).

### **4.7. Study Variables**

**4.7.1. Dependent Variable:** The dependent variable was nutritional status in children 6-59 months years old.

#### **4.7.2. Independent Variables**

**1. Socio-demographic Variables :** religion, sex, economic status, family size, number of livestock owned, landholding size, the occupation of mother, marital status of the mother, age of the mother, child sex, child age, and agro-ecology.

**2. Maternal and Child characteristics:** immunization status of the child ,antenatal care, history of diarrhea, exclusive breast feeding, cough, maternal education, frequency of complementary foods, perceived child birth weight.

**3. Environmental Health conditions:** safe water supply, availability of latrine, type of latrine, presence of window, type of the floor.

### **4.8. Data Quality Control**

Two days training was provided to data collectors and supervisors. Data was collected under the supervision of the principal investigator. Incomplete questionnaires were completed by making second visits to the homes. Pre-test was done before the actual data collection to see for the accuracy of questions and responses and to estimate time needed. Weighing scales was calibrated with known weight object regularly. The data collectors also have standardized the anthropometric measuring tools in the training sessions to maintain the uniformity of measurements. The scales indicator was checked against zero reading after weighing every child. The questionnaire was first prepared in English and then translated to Afan Oromo and

back translated to English by language expert to maintain the consistency of the contents of the instrument.

#### **4.9. Data Management and Analysis**

First the data was checked for completeness and consistency. Then it was entered and coded in the computer using Epidata version 3.1 software. WHO Anthro software was used to convert weight, height/length and MUAC values into Z-scores of the indices; H/A, W/H and W/A taking age and sex into consideration using WHO child growth standard.

Then, the data was exported to SPSS 16.0 program for analysis; descriptive summary using frequencies, proportions, graphs and cross tabs used to present study results. Binary logistic regressions were used to see the strength of association between independent and dependent variables. Variables which are significant at p-value less than 0.25 in bivariate analysis were candidate for multivariate analysis. Multivariate logistic regression analyses, based on UNICEF's analytical framework, was conducted to identify determinants of nutritional status i.e. independent variables that have a significant role in influencing nutritional status and to account for possible confounding factors using SPSS standard Backward Stepwise method. The degrees of association between dependent and independent variables were assessed using OR and 95% CI. P-value less than 0.05 was considered as statistically significant.

#### **4.10. Operational Definitions**

**Diarrhea;** A child with loose stools for three or more times in a day or a sign of dehydration

**Acute Respiratory Illness;** A child with cough and fast breathing or difficulty in breathing

**Family size;** refers total number of people living in a house during the study period.

**Income;** It is periodical monthly earning from one's business, lands, work, investment etc.

**Malnutrition;** refers to under nutrition or deficiency in protein-energy nutrition.

**Stunting:** H/A less than the international median WHO child growth reference value by more than two standard deviations: below -3SD is severe stunting.

**Wasting:** W/H less than the international median WHO child growth reference value by more than two SD.

**Severe wasting:** W/H below -3SD or less than 70% of the median WHO reference values

**Underweight:** W/A less than two SD below the international median WHO child growth reference value.

#### **4.11. Ethical clearance**

Letter of ethical clearance was obtained from Research Ethics Committee of Jimma University. Letter of permission was obtained from Bule Hora Woreda health office for health centers and letter of permission also obtained from these health centers for the health posts and kebele administrators. Each respondent was informed about the objective of the study and privacy during the interview. Finally verbal consent was requested from the study participants selected for interview in the study immediately before the data collection.

#### **4.12. Dissemination of the finding**

The result of the study will be presented to Jimma University community as part of MPH thesis and it is disseminated to Jimma University, College of public health and medical science, department of Epidemiology, Oromia Regional health bureau, Borena zone health department ,Bule Hora health office and to the targeted health facilities and to Non-governmental organizations working on this area. Further attempt will be made to publish it on national and international scientific journals.

## **Chapter Five-Result**

### **5.1. Socio-demographic conditions**

From the total 796 planned study participants, complete response was obtained for 778(97.7%). Female headed HHs were 8.6% and 91.8% of the respondents were married. Average family size was 6.27 persons ( $\pm 2.61$  SD) while 55% of the HHs have more than five family members. About 47.9% of the HHs had two under five children and 5.7% of the HHs had three under five children.

Concerning educational status, 63.9% mothers of the children were illiterate, 30.7% have primary education, 4.4% were secondary education, and 1.1% were certificate or diploma holders. And 40.4% of the fathers of the children were illiterate, 50.4% have completed primary education, 5.0% completed secondary education and the rest 4.2% were a certificate or diploma holders.

About 65.2 % of the mothers were housewives, 16.3% merchants, 13.1%farmers, 1.3% government employee and 1.5% private employee. Majority of the respondents were Oromo ethnic group (89.5%) and 6.4 were Gedeo. Their religion was; 85.3% Protestants, 5.9% Orthodox Christian, 5.4% Muslim, 1.8% catholic and 1.5% were following other religions. Farm land ownership was 68.5% and 57% of these land owners had 0.5 hectare or less. Animal ownership was 64.9%(Table 1).

**Table 1; Distribution of Socio-demographic characteristics of study participants, Bule Hora Woreda, Borena Zone, Oromia Regional State, 2013**

## 5.2 Child characteristics and Caring practices

From the total children, 50.6% were males and mean age was 28( $\pm$ 14.6SD) month for both sex. Nearly half (46.4%) of the children were with second to fourth birth order. Place of delivery was at home for 89.1% of the children. Birth weight was small for 4.0% of the children, very small for 4.4%, average for 63.7%, very large for 11.7% and large for 16.2%.

**Table 2; Distribution of Child characteristics, Bule Hora Woreda, Borena Zone, Oromia Regional State, 2013**

<b>Variables</b>		<b>Frequency(n)</b>	<b>Percent (%)</b>
<b>Child sex(n=778)</b>	Male	384	49.4
	Female	394	50.6
<b>Child age category(n=778)</b>	6-11	123	15.8

	2 episodes	84	22.3
	$\geq$ 3 episodes	25	6.6
<b>Fever (n=778)</b>	Yes	41	5.3
	No	737	94.7

The study finding also shows that 32.7 % of children were exclusively breastfed for less than six months. The frequent health problem of the children was diarrhea for 41.8% children and 25.1% had diarrhea in the last two weeks. About 3.3% of the children showed symptoms of acute respiratory infection (ARI) in the past two weeks prior to the survey (Table2).

Concerning immunization, 2.1% of the children did not receive any form of vaccine and 54.3% were fully immunized .Only 51.5% of the children received vitamin A in the past six months prior to data collection. According to the study finding pre-lacteal feeding was given for 12.1% (water for 8.2%, milk 3.1% and butter for 0.8%) of the children and 2.4% mothers squeezed out the first milk. About 67.1% of the children visited health facility for illness care and 50.8% of the children took bath in every other day to week period (Table 3).

### 5.3 Maternal conditions

As indicated in table 4, mean age of mothers was 31.5( $\pm$ 6.0 SD) years and mean age of mother at first child birth was 20.4 ( $\pm$  2.3 SD) year. Mothers who gave first birth at the age 18 and less years were 24.6%. Average total children born to a mother was 4.2 children ( $\pm$ 2.5 SD); and 37.9% of the mothers gave birth of five and above children.

The study finding also showed that out of the mothers interviewed 27.5% of them did not attend ANC service during their pregnancy. About 92.9% of mothers had information about family planning methods but only 49.8% of them used family planning. No extra food was taken from the usual time during pregnancy and lactation for 65.9% of the mothers (Table 4).

**Table 4; Distribution of Maternal conditions, Bule Hora Woreda, Borena Zone, Oromia Regional State, 2013**

<b>Variable</b>		<b>Frequency(n)</b>	<b>Percent(%)</b>
<b>Mothers age at first birth (n=778)</b>	15-18	191	24.6
	>18	587	75.4
<b>Maternal age category (in years)(n=778)</b>	15-19	10	1.3

	No	363	50.2
<b>Extra food intake during pregnancy/lactation(n=778)</b>	Yes	513	65.9
	No	265	34.1

## 5.4 Environmental conditions

According to the study finding, 61.9% of the households were getting water from tap water. Majority of the HHs (80.1%) have a latrine. Traditional private pit latrine with wooden slab was the commonest type (86.7%) being utilized. Housing type with corrugated iron sheet roof were 68.6% and 74.3% of the houses had windows (Table 5).

**Table 5; Distribution of Environmental conditions, Bule Hora Woreda, Borena Zone, Oromia Regional State, 2013**

Variables		Frequency(n)	Percent (%)
Water source (n=778)	River	48	6.2
	Pond	30	3.9
	Unprotected spring	51	6.6
	Protected spring	124	15.8
	Private well	46	5.9
	Tap water	479	61.6
	Per capita water use(n=778)	≤20 liter	15
	20-40 liter	635	81.6
	>40	128	16.5
Availability of latrine (n=778)	Yes	623	80.1
	No	155	19.9
Type of latrine (n=623)	Private pit with wooden slab	540	86.7
	Others *	83	13.3

	Corrugated iron sheet	534	68.6
Presence of window(n=778)	Yes	578	74.3
	No	200	25.7

\* Private pit with cement slab, Shared latrine, VIP latrine,

## 5.5 Nutritional status of the children

Prevalence of stunting, underweight and wasting was 47.6%, 29.1% and 13.4% respectively.

Prevalence of severe stunting, underweight and wasting was 20.2%, 6% and 3.9% respectively.

MUAC measurement also indicated that 10% of the children were malnourished (<12.5 cm).

There was no child with nutritional edema.

**Table 6; Prevalence of Child Malnutrition, Bule Hora Woreda, Borena Zone, Oromia Regional State, 2013**

<b>Malnutrition indicators</b>	<b>Frequency (%)</b>
Stunting	370 (47.6)
Severe stunting	157(20.2)
Underweight	227(29.2)
Severe underweight	47(6.0)
Wasting	104(13.4)
Severe wasting	30(3.9)
Low MUAC for age (z-score<-2)	95(12.2)
Low MUAC for age (z-score <-3)	18(2.3)
Moderate acute malnutrition ( MUAC $\geq$ 11.5cm &< 12.5cm)	60(7.7)
Severe acute malnutrition ( MUAC<11.5cm)	18(2.3)
MUAC<12.5	78(10)

Prevalence of stunting was highest in children of 24-35 years age and underweight was highest in the age group of 48-59 months. The prevalence of stunting was increasing 6-11 to 24-35 age category and the prevalence of underweight was increasing from 6-11 month (23.6%) to 48-59(39.6%) month age category, in the opposite the prevalence of wasting was decreasing from 6-11(16.5%) to 24-35 (7.5%) age category (Table 7).

**Table 7; Prevalence and number of 6-59 months children affected by malnutrition by age category, Bule Hora Woreda, Borena Zone, Oromia Regional State, 2013**

Age Category in month	Stunting	Severe stunting	Wasting	Severe Wasting	Underweight	Severe Underweight
	No (%)	No (%)	No (%)	No (%)	No (%)	No (%)
6-11	29(23.6)	12(9.8)	20(16.5)	3(2.4)	29(23.6)	3(2.4)
12-23	104(55.0)	49(25.9)	20(10.8)	2(1.1)	47(24.9)	11(5.8)
24-35	98(61.2)	41(25.6)	12(7.5)	1(0.6)	43(26.9)	6(3.8)
36-47	74(39.4)	25(13.3)	33(17.7)	19(10.1)	61(32.4)	13(6.9)
48-59	65(55.1)	30(25.4)	19(16.4)	5(4.2)	47(39.6)	14(11.9)
Total	370(47.4)	157(20.2)	104(13.4)	30(3.9)	227(29.2)	47(6.0)

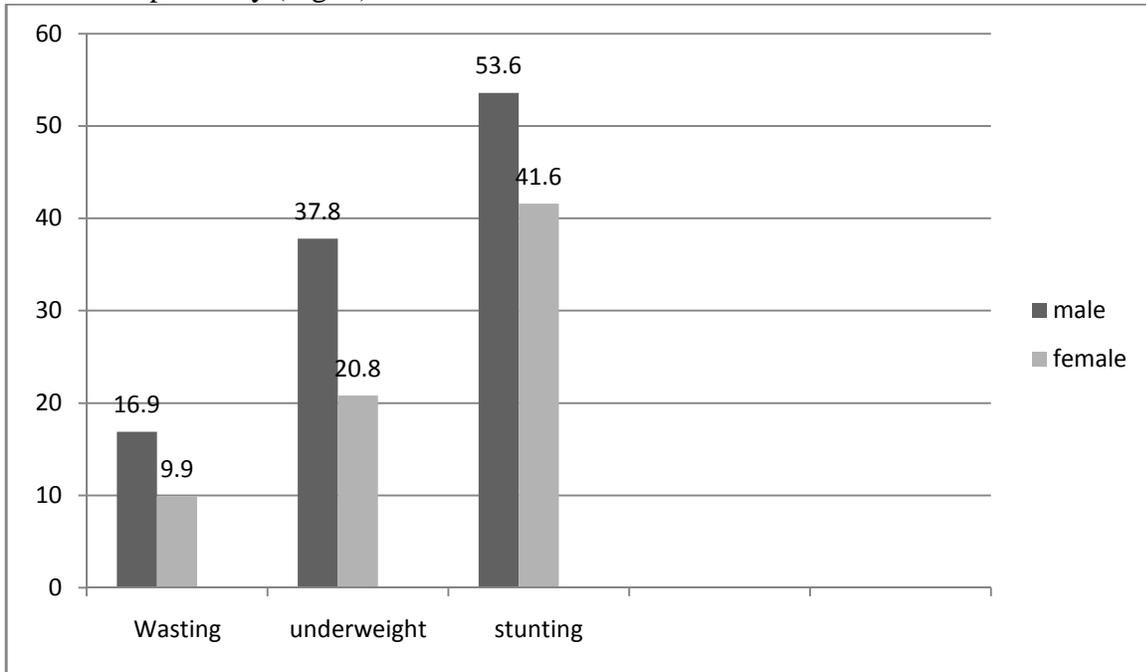

Table 8 below shows that out of 157 severely stunted children 105(66.9%) were males and out of 47 severe underweight children 33(70.2%) were males. And also the study shows that the prevalence of stunting ( height for age between -2 and -3SD of the median WHO reference values) is high in female children (52.6%) than males but severe stunting (height for age below -3SD of the median WHO reference values)was highest in males (66.9%).Prevalence of underweight and severe underweight was highest in males (62.2% underweight, 70.2% severe underweight) than females (37.8% underweight, 29.8% severe underweight).

Prevalence of wasting was also high in males than females. According to the finding out of 74 children with weight for height z-score between -3 and  $\leq -2$  (weight for height between -2 and -3SD of the median WHO reference values) 49(66.2%) males and 16(53.3%) were females. Severe wasting (weight for height below -3SD of the median WHO reference values) also high in males 16(53.3%) than females 14(46.7%).

**Table 8; Prevalence and number of 6-59 months children affected by stunting, underweight and wasting by sex category, Bule Hora Woreda, Borena Zone, Oromia Regional State, 2013**

		Child sex		Total No (%)
		Male	Female	
		No (%)	NO (%)	
<b>Height for age z-score</b>	Normal( z-score >-2)	178(43.6)	230(56.4)	408(100)
	stunting (z-score -3 up to≤-2)	101(47.4)	112(52.6)	213(100)
	Severe stunting (≤-3)	105(66.9)	52(33.1)	157(100)
<b>Weight for age z- score</b>	Normal (z-score >-2)	239(43.3)	312(56.6)	551(100)
	underweight (z-score -3 up to≤-2)	112(62.2)	68(37.8)	180(100)
	Severe underweight (z-score ≤-3)	33(70.2)	14(29.8)	47(100)
<b>Weight for height z-score</b>	Normal (z-score >-2)	319(47.3)	355(52.3)	674(100)
	Wasting (z-score -3 up to≤-2)	49(66.2)	25(33.8)	74(100)
	Severe wasting (z-score ≤-3)	16(53.3)	14(46.7)	30(100)

The study also identified the nutritional status of under-five children by sex. The prevalence of wasting, underweight and stunting was higher in males than females. The prevalence of stunting, underweight and wasting was 53.6%, 37.8%, and 16.9% in males and 41.6%, 20.8% and 9.9% in females respectively (Fig. 3).

**Figure 3- Nutritional Status of 6-59 years age children by sex, Bule Hora Woreda, Borena Zone, Oromia Regional State, 2013**

## 5.6 Determinants of under-five Nutritional Status

Nutritional status among under five years age children was analyzed in for association with some selected variables related to demographic, socio-economic, child, maternal and environmental aspects.

According to bivariate analysis; maternal education ,paternal education , child sex, total number of children ever born to a mother, having livestock, birth order, having diarrhea in the last two weeks prior to data collection, giving pre lactation food, exclusive breast feeding, bath taking ,visiting health facility for ANC service ,using family planning methods and availability of latrine were significantly associated with underweight. In multivariate analysis only paternal education, child sex, presence of diarrheal disease in the past two weeks and total number of children ever born to a mother were have significant association with underweight.

The same to that of underweight many variables were significantly associated with stunting in bivariate analysis. Child sex, presence of diarrheal disease in the past two weeks, maternal use of family planning methods and pre-lacteal feeding were significantly associated with stunting in multivariate analysis. Age at which additional food started, presence of diarrhea in the past two weeks and maternal use of family planning methods were significantly associated with wasting in multivariate analysis.

Table 9 shows that the odds of being male was 2.5 times (OR=2.5, 95%CI: 1.5-4.1) as high as females to become underweight. The study finding also shows that having diarrhea in the past two weeks as a predictor of child to become underweight. The odds of children having diarrhea in the past two weeks prior to the data collection was 3.9 times (OR=3.9,95%CI: 2.2-6.8) as high as children who did not have diarrheal disease in the past two weeks prior to the data collection to become underweight.

Paternal lack of education was also one of the important predictors of children being low weight for age. According to the multivariate done, the odds of children whose fathers were uneducated

was 6.7 times (OR=6.7, 95%CI: 10.76-62.2) as high as children from educated fathers to become underweight.

The finding shows that total number of children ever born to a mother was also an important predictor for underweight. The odds of children born to a mother who gave birth to children of more than four was 1.8 times as high as children born to a mother who gave birth to less than four children to become underweight (Table 9).

**Table 9; Factors associated with Underweight in children of 6-59 month age , Bule Hora Woreda,2013**

Variables		Underweight		Crude OR (95% CI)	Adjusted OR (95%CI)
		Yes	No		
<b>Child sex</b>	Male	145	239	2.3(1.6-3.1)*	2.5(1.5-4.1)*

Table 10 below shows that multivariate analysis of some selected variables which predict low height for age. According to the analysis, the odds of being male was 2.8 times (OR=2.8, 95%CI: 1.5-5.3) as high as females to become stunted. Presence of diarrheal disease in the past two weeks prior to data collection also factor which influences child nutritional status. The odds of children having diarrheal disease in the past two weeks was 2.5 times (OR=2.5, 95%CI: 1.2-5.3) as high as children who did not have diarrheal disease in the past two weeks to become stunted.

Prevalence of stunting was higher in children who provided pre lacteal feeding. The odds of children who had given pre lacteal feeding was 3.8 times (OR=3.8, 95%CI: 1.2-12.2) as high as children who had not given a pre -lacteal feeding to become stunting. Maternal uses of family planning methods have significant association with chronic malnutrition. Mothers who did not use family planning methods were also the other variable which is significant at multivariate analysis. The odds of children born to mothers who did not use family planning methods was 1.5 times (OR=1.5, 95%CI: 1.0-2.1) as high as children whose mothers used family planning methods to become stunted (Table 10).

## **Chapter- six- Discussion**

Prevalence of child malnutrition was high in the Woreda. This study noted that there were unprecedented levels of malnutrition among children under the age of five years in the Woreda attributed to maternal and child, behavioral, cultural and socio-economic factors. This might be also an obstacle in the achievement of the fourth millennium development goal which intends to reduce infant and young child mortality by two-thirds from 1990 to 2015.

Even though the prevalence of underweight and stunting was somewhat different (36.6% underweight and 42.2% stunted) the result of our study was comparable to prevalence of wasting (14.1%) conducted in rural kebeles of Haramaya (23). This difference might be due to socio-economic and cultural factors between the two communities and also in their study children less than 6 months of age were included.

This study also revealed that prevalence of child malnutrition was high in the Woreda in comparison to the EDHS 2011 report (44% stunting and 10% wasting)(14). The discrepancy might be due to small sample size compared to that of EDHS and children below the age of six months were not included.

Except for that of wasting, the risk for stunting and underweight increased as age increases in both sexes up to the age of three and then relatively decreases as age increases. This is in agreement with the report from Democratic Republic of Congo which showed the nature of malnutrition to be strongly dependent on age, EDHS 2011 and the study conducted in India by Shubhada S. et al which suggested that it is due to improper weaning and recurrent infections which makes this age group more vulnerable (14,22,35). The other possibility could be inappropriate weaning method at earlier age and then later after the age three the improvement seen may be due to the fact that the child can demand and take type of food when he/she need. The other possible reason is due to the cumulative effect of chronic malnutrition. As age increases it is expected that the rate of stunting and underweight increases. However, the pick period is around the age of 2 years.

There was very high prevalence of wasting in the study area alarming to increased risk of death to children. It signifies acute nutritional problem due to illness and/or recent food shortage. High chronic malnutrition also signifies children's failure to grow; impact on both physical and mental capacity of the affected children. Infections play a major role in the etiology of PEM because they result in increased needs and a high energy expenditure, lower appetite, nutrient losses due to vomiting, diarrhea, poor digestion, mal-absorption and the utilization of nutrients and disruption of metabolic equilibrium (24). In this study presence of diarrhea in the last two weeks prior to data collection was the main contributing factors for stunting, underweight and stunting. This study was in agreement with the study conducted in West Gojjam and Vietnam (29,36).

The prevalence of all the three types of malnutrition was higher among males than females and the prevalence of stunting, an indication of chronic malnutrition, was higher compared to wasting and underweight in the study area. A finding of this study was in agreement with the studies conducted by Nnyepi M. et al, Olack B .et al and Shubhada S.et al, (21, 22, 27).The probable reason for the males to be malnourished than females might be due to the increased attention being paid to female children, as well as reduced care and weaned male children.

Pre-lacteal feeding was also a risk factor for being stunted. This study revealed that children who provided pre lacteal feeding were more likely to be stunted than children who did not provided pre lacteal feeding. This study is consistent with the study conducted in Haramaya rural kebeles, Gondar University hospital and west Gojjam (22, 29,32).The higher risk of stunting among children who were fed pre-lacteal feed might be due to its negative impact on breastfeeding and when children are not breastfed appropriately, they are at high risk of under-nourishment.

In studying the correlates of under nutrition in children under five years of age, this finding also revealed that a negative relationship between mothers use of family planning methods and nutritional status (stunting and wasting) of children exists in this study population. This study was in line with the report of EDHS 2012 which shows that there is an inverse relationship between the length of the preceding birth interval and the proportion of children who are stunted. The longer the interval, the less likely it is that the child will be stunted(14).The probable reason is

that when there are too many children who are closely spaced in the family, there may be the tendency for malnutrition to occur.

This study also identified that children with age group 6-59 months born to a mother who gave birth to more than four children were more likely to be underweight when compared with children from a mother who gave birth to less than four children. This study was supported by the study conducted in Vietnam and Bangladesh which showed that families with more children experience more economic strain for food consumption and hence they are more likely to suffer from poor nutritional status. In other words, inadequate allocation of household resources among many children may lead to the low nutritional status. Particularly poor families cannot fulfill the nutritional requirements of the children. Families with more children generally devote less time to take care of their children (30, 32, 36).

Age at which additional food was given was also a significant predictor for being wasted. Children who started additional food before the age of six months were more likely to be wasted when compared with the children who started additional food at the age of six month. This study was in line with the study conducted in Vietnam and Ludhiana which showed that children who exclusively breast fed for <6 months were more likely to be wasted when compared with those exclusively breast fed for  $\geq 6$  months (28, 36).

The finding of this study showed that children from uneducated father were more likely to be underweight when compared with children of educated fathers. This study is consistent with study conducted in Gondar University hospital by Amsalu.S and Tigabu. Z and Bangladesh by Mohammed I.et al which identified children from uneducated fathers were positively associated with child malnutrition. It is argued that fathers with higher status in the society have the ability to make decisions that improve the nutritional status of children while those with low status do not (30, 32).

## **Chapter – Seven- Limitation of the Study**

As the study is cross-sectional in design, it neither represents seasonal variation of nutritional outcomes particularly to the wasting status nor establishes causal relationship. Dietary aspect which is the immediate determinant of nutritional status is not included in this study. The measurements may not be accurate due to subjective responses and recall bias. Age determination was difficult since there was no birth registration in the area.

## **Chapter- Eight- Conclusions and Recommendations**

### **Conclusion**

Based on the finding of this study it can be concluded that; acute malnutrition is at critical stage alarming. High prevalence of stunting in the area is also of particular concern in the Woreda. In the Woreda prevalence of stunting, underweight and wasting was 47.6%, 29.2% and 13% respectively and that of severe stunting; underweight and wasting was 20.2%, 6.0% and 3.9% respectively.

The study also identified the predictors of child malnutrition. Being male, presence of diarrheal disease in the last two weeks, mothers who did not use family planning and pre-lacteal feeding were the important contributing factors of stunting. Being male, total number of children ever born to a mother, presence of diarrhea in the last two weeks and uneducated fathers were significantly associated with underweight. Presence of diarrhea in the last two weeks, age at which additional food given and mothers who did not use family planning were the important predictors for wasting.

### **Recommendations**

#### **For Bule Hora Woreda Health Office:**

- Prevention and control of diarrheal disease through improving access to safe and adequate water supply, immunization, housing, sanitation and hygiene practices.
- Intervention should focus on improving promotion of nutrition education and utilization of family planning.
- Promotion of better child and maternal caring practices.

#### **For Researchers :**

- Further research in dietary assessment is required.

## Annex -2 – English version Questionnaire

This questionnaire is prepared for collecting information on child nutritional status and determinants at household level in Bule Hora Woreda of Borena Zone.

Consent

Greetings

### Introduction;

My name is \_\_\_\_\_ . I am working as data collector in a survey conducted by the collaboration of Jimma University, college of medical science and public health to assess child nutritional status and associated factors.

Your name will not be written on this form and will never be used with any information you may tell me. You don't have to answer any questions that you don't want to answer and you may end this interview at any time you want. However, your honest answer to these questions is very important for the purpose of the study. We would very much appreciate your participation in this survey by genuinely responding to the interviews. Would you be willing to participate? It would take \_\_\_\_\_ minutes to complete the questionnaire

Signature of the interviewer certifying that informed consent has been given verbally by respondent\_\_\_\_\_.

001. Questionnaire identification number /\_\_\_\_\_/\_\_\_\_\_/

002. Interviewer code\_\_\_\_\_ Name\_\_\_\_\_

003. Date of interview\_\_\_\_\_

004. Residence; 1. Urban 2. Rural

005. Result: 1. Completed 2. Partially completed 96.Others (Specify)

Checked by supervisor; Name\_\_\_\_\_, Signature\_\_\_\_\_

Part I Socio- demographic Variables			
No	Question	Response	Skip to/remark
101	Head of the House Hold	1. Male 2. female	
102	Marital status	1. Married 2. Divorced 3. Widowed 4. Separate 5. Single	
103	Total family size (How many person live in the HH?)	In number_____	

104	How many children <5 year live in the HH	In number _____	
105	<b>Maternal Education</b> What is the highest grade you completed?	Grade _____ 1. Technical/Vocational certificate 2. Diploma 3. Degree 96. Other (specify)	
106	<b>Paternal Education</b> What is the highest grade he completed?	Grade _____ 1. Technical/Vocational certificate 2. College/University Diploma 3. College/University Degree 96. Other (specify)	
107	<b>Occupation of mother</b> (More than one answer is possible)	1. Housewife only 2. Farmer 3. Merchant/Trade 4 Private Organization employee 5. Government employee 6. Daily laborer 96. Other (specify)_____	
108	<b>Occupation of husband</b> (More than one answer is possible)	1. Farmer 2. Government employee 3. Merchant/Trade 4. Private Org. employee 5. Daily laborer 96. Other (specify)_____	
109	Monthly income of the HH	_____ Birr	
110	Who decides how the money you earn will be used?	1. Mainly spouse 2. Mainly husband 3. Only husband 4. Both jointly	
111	Do you have some control and power (autonomy) in decision-making?	1. Yes 2. No 99. Do not know/not sure/	
112	Do you have livestock, herd or farm animal?	1. Yes 2. No	If, no skip to 114
113	If yes, how many? - Milk cow, Oxen and bulls? - Goat?	_____ number _____ number	

	- Sheep? - Chicken? - Horse, donkey mule? In total	____ number ____ number ____ number ____ number	
114	How many agricultural lands do you have?	1. Do not have 2. _____(local unit) ( Hectar) 99. Do not know/not sure	
115	Ethnicity	1. Oromo 2.Amhara 3. Tigre 4. Gurage 5.Burji 96. Others (specify)	
116	What is your religion?	1. Protestant. 2.Muslim 3. Orthodox 4. Catholic 96. Others(specify)_____	
<b>Part II CHILD CHARACTERISTICS (Randomly select if there are more than one under five)</b>			
201	Child's sex	1. Male 2. Female	
202	Child's age	____ Months	
203	Birth order	____ th	
204	Place of delivery	1.Home 2.Health institution 96. Other (specify)	
205	Gestational age at birth	1. Less than 9 Months 2. At 9 months 3. Greater than 9 Months 99. Do not know /Not sure/	
206	Was your child weighed at birth	1. Yes 2. No	If no, skip to 208
207	How much was the weight?	____ Grams (card/recall?)	
208	When (NAME) was born, How big was he/she?	1. Very large 2. Larger than average 3. Average 4. Smaller than average 5. Very small 99. Don't know	
209	Type of birth	1. Single 2. Multiple/Twin/	
210	Did you have plan (want) to give birth of the child at health facility?	1. Yes 2. No	
211	Does the child ever been immunized?	1. Yes 2. No	If no, skip to 213
212	Vaccines received (See card, if no card available ask them to recall) (More than one answer is possible)	1. BCG only (See Scar) 2. Penta (No of dose____) 3. Measles 4. No card found	
213	Vitamin. A supplementation in the	1. Yes 2. No	

	past six months?	98. Don't know/not sure	
214	What do you think is the frequent health problem to the child?	_____ Disease/s 99. Don't know	
215	Has the child had diarrhea in the last two Weeks?	1. Yes 2. No 99. Do not know/not sure	If no, skip to 217
216	How frequent in a year?	1. Once 2. Twice 3. 3-4 times 4. >5 times	
217	Has the child been ill with fever at any time in the last two weeks?	1. Yes 2. No 99. Don't know/not sure	
218	Presence of respiratory disease in the last two weeks	1. Yes 2. No 99. Do not know/not sure	
219	Has the child get sick with measles in the last year?	1. Yes 2. No 3. Do not know/not sure	
220	Presence of oedema on the child (Observe)	1. Yes 2. No	
<b>PART THREE: CHILD CARING PRACTICE</b>			
301	Did you ever breast fed the child (NAME)?	1. Yes 2. No	
302	How long after birth did you first out the child to breast feed?	1. Immediately 2. ___Hours (If less than 24 hours record hour) 3. ___ Days 99. Don't know/not sure/	
303	Did you give the child (NAME) pre-lactation food/fluid?	1. Yes 2. No	If no, skip to 305
304	If yes, what did you gave him (her)?	1. Water 2. Butter 3. Milk 96. other (Specify)	
305	Did you squeeze out and throw the first milk?	1. Yes 2. No	
306	Are you still breastfeed?	1. Yes 2. No	If no, skip to 309
307	How many times in the last 24 hours you breastfed?	_____ Times	
308	Do you breast feed in the night?	1. Yes 2. No	
309	Did you give the child additional food or fluid other than breast milk in the past 48 hours?	1. Yes 2. No	If no, skip to 314
310	If yes, what ingredients you gave? (More than one answer is possible)	1. Cow's milk 2. Butter 3. Sugar solution. 4. Formula milk. 96. Other (specify)_____	
311	How many times in 24 hours?	_____ times	
312	At what age did you start feeding other additional food?	_____ Months	
313	What do you use to feed the child?	1. Bottle 2. Cup 3. Spoon 96. Other (specify)	

314	How many months did you breast-feed the child?	_____ Months 99. Don't know/not sure/	
315	For how many months did you exclusively breast-fed the child?	_____ Months 99. Don't know/not sure/	
316	Who is usually taking care of the baby feeding?	1. Mother 2. Sister 3. Grand mother 4. House maid 96. Other (specify)	
317	During the illness, has the child feeding practice changed?	1. Yes 2. No	If no, skip to 319
318	How could the practice changed?	1. preventing from breast 2. preventing from giving food 3. Providing additional food 96. Other (specify)_____	
319	How frequent you wash utensils used for child feeding?	1. Twice daily 2. Once daily 3. Every other day. 4. Immediately after use 96. Other (Specify)	
320	Bath taking of the child	1. Daily 2. Weekly 96. Other (Specify)	
321	How did you usually treat your child when get sick?	1. Usually home treatment 2. Taking to traditional healers 3. Taking to Health institution 96. Other (Specify)	
322	Have you ever take your child to health institution for sickness?	1. Yes 2. No	If no, go to part 4
323	How many times have you ever taken the child to health institution getting sick?	_____ Times 99. Don't know/not sure	
<b>PART FOUR : MATERNAL CHARACTERSTICS</b>			
401	Mother's age in years	Year completed_____	
402	Age at first birth	_____ Years	
403	Age when the youngest child was born	_____ Years	
404	Total number of children ever born?	In number _____	
405	Pre-pregnancy weight (the child under the study)	In kilogram_____ 99. Do not know/not sure/	
406	During pregnancy or lactation, did you consume extra food? (the child under the study)	1. Yes 2. No	

407	Health status during the pregnancy	1. Good 2. Not good/sick	
408	Did you visited health facility for ANC?	1. Yes 2. No	If no, skip to 411
409	At what months of the pregnancy you started ANC?	At _____ months 99. Don't know/not sure	
410	How many times you visited health facility for ANC during the pregnancy?	_____ times	
411	Do you know about family planning?	1. Yes 2. No	If no skip to 415
412	Have you ever used family planning methods?	1. Yes 2. No	If no, skip to 415
413	Which method have you ever used? (More than one answer is possible)	1. Pills 2. Depo-Provera 3. Norplant 4. condom 96. other (Specify)	
414	Do you use it now?	1. Yes 2. No	
415	When do you usually wash your hands? (More than one answer is possible)	1. After latrine use 2. Before preparing food 3. Before serving food 4. After cleaning child feces 96. Other (specify)	
416	How do you wash your hand?	1. Using water only 2. Using soap some times 3. Using soap always 4. Using ash some times	
417	What do you think your child physically looks?	1. Thin 2. Tall 3. Heavy 4. Normal 5. Small	
418	For how long do you think should a child exclusively be breast-fed?	In months _____	
<b>PART FIVE: ENVIRONMENTAL CONDITIONS</b>			
501	What is your main source of drinking water?	1. River 2. Pond 2. Un protected spring. 3. Protected spring. 4. Private well 5. Public tap 96. Other (specify)	
502	Amount of water used in the household daily	In liters _____	
503	How long does it take you to go and come back to fetch water?	In minutes _____	
504	Do you treat water in any way to make it safer?	1. Yes (Specify) _____ 2. No	
505	Do you have latrine?	1. Yes 2. No	If no skip to 507

506	Type of latrine you use? (Observation)	1.Private pit / wooden slab 2. Private slab / cement slab 3. Shared latrine/wooden slab 3. Shared VIP latrine 96. Other (Specify)	
507	How do you dispose garbage?	1. Open field disposal. 2. In a pit 3. Common pit 4. Composting 5. Burning 96. Other (specify)	
508	Type of House (Observation)	1.Tukul/thached 2. Corrugated Iron Sheet 96. Other(Specify)	
509	How many rooms for use by the member of your household? (Excluding kitchen and store)	_____ in Number	
510	Type of house floor (Observation)	1. Earth /Soil/. 2. Cement/Brick 3. Wooden/Bamboo 4. Ceramic 96. Other(Specify)	
511	Floor area of the house per person	_____Km <sup>2</sup>	
512	Presence of windows (Observation)	1. Yes 2. No	If no ,skip to 514
513	If yes, how many?	1. One 2. ≥ Two	
514	Do you have separate room which is used as Kitchen?	1. Yes 2. No	
515	If you have livestock, do you have separate room for them?	1. Yes 2. No	
516	What type of fuel do you mainly use for cooking?	1. Wood 2. Kerosene 3. Electricity 4. Animal dung 96. Other(specify)
