Abstract

Background; Low birth weight which is associated with a wide range of both short- and long-term consequences remains a formidable public health challenge for the 21st century. Despite the presence of different prevention options and efforts it is estimated that 15% to 20% of all births worldwide are low birth weight. Although several studies have been conducted in different countries including Ethiopia, most of the studies conducted didn't considered the food security status, environmental related and maternal dietary diversity related factors.

Objective: - To identify determinant factors of low birth weight among newborns.

Method; Facility based unmatched case control study was employed from March 15, 2020 to June 16, 2020 among 84 cases and 168 controls in selected public health facilities of Silte zone. Cases were newborns with birth weight less than 2500gm and controls were newborns with birth weight greater than 2500gm. The data were collected using semi structured, pretested interviewer administered questionnaire. Multivariable logistic regression analysis was carried out to identify independent determinants of Low birth weight, and variables with a p-value <0.05 were considered to be statistically significant.

Results: The mean birth weight was 2154.94gm \pm 233.43 gm SD for cases and 3022.92gm \pm 311.88 gm for controls. not iron and folate supplementation during pregnancy(AOR=4.175, 95%CI;(1.437,12.300), not taking additional meal(AOR= 3.096, 95%CI(1.278,7.502)), maternal hemoglobin level <11g/dl, (AOR = 5.213, 95% CI (1.923,14.130), house hold food insecurity (AOR= 6.853, 95%CI;(3.008, 15.613))and inadequate minimum dietary diversity of women(AOR=4.131(1.403,12.158))were found to be independent determinants of low birth weight.

Conclusion and recommendations: Lack of iron and folate supplementation during pregnancy, maternal meal frequency during pregnancy, maternal hemoglobin level, Food insecurity and inadequate Minimum dietary diversity of women were significant determinants of Low birth weight. The importance of additional food and iron and folate supplementation during pregnancy, and proper identification of high risk mother needs to be strengthened effort to reduce incidence of Low birth weight infants. In addition, working with agricultural sector, Women affairs targeting pregnant women in improving women dietary diversity. Health extension workers and health professionals in each health facility working at ANC clinic should give advice pregnant mothers about use and adherence of iron folate, additional meal, and dietary diversity.

Key words; Low birth weight, Preterm, Newborn

Acknowledgment

First of all, I give thanks to Allah that granted me the health, the ability, the zeal, and the courage to prepare this thesis. Then I would like to present my heartfelt thanks to my Advisors Dr. Beyene Wondafrash and Mr.Nurezeman Gali for their intensive guidance, being available and sparing their valuable time to help me in all possible ways for this thesis & I would also like to thank Jimma University Institute of Health, Department of Nutrition and dietetics for providing me this golden opportunity to develop this thesis. My acknowledgment also extends to Silte Zone Health Department, each health facilities, data collectors, my families and friend for their Cooperation and support.

CHAPTER ONE

1 INTRODUCTION

1.1 Background

Birth weight is the first weight of the fetus or newborn measured soon after the birth. Measurement should ideally be done within the first hour of life to avoid significant postnatal weight loss (1). Based on this new born is classified as large for gestational age normal for gestational age and small for gestational age(2). World health organization (WHO) defines Low birth weight (LBW) as weight at birth of less than 2500 gram. The more severe form of it is very low birth weight (VLBW) which is birth weight of less than 1500 grams, and the worst is extremely very low birth weight that is birth weight of <1000 gram. It is the type of small for gestational age (SGA) which lowers survival status of new born and increase risk of perinatal death and severe disability (3,4).

Duration of gestation and intrauterine growth rate determines birth weight. Low birth weight is thus caused by either a short gestation period or retarded intrauterine growth or a combination of both. Prematurity is a gestational age of less than 37 weeks. Whereas intrauterine growth restriction (IUGR) is defined as: birth weight less than 10th percentile for gestational age; birth weight less than 2500 g and gestational age greater than or equal to 37 weeks; and birth weight less than 2 standard deviations below the mean value for gestational age(5) In turn Intrauterine growth restriction and Prematurity results from complex and multiple factors. While Intrauterine growth restriction is the result of poor maternal nutritional status at conception, low gestational weight gain, short maternal height and infectious diseases during pregnancy, prematurity is caused by maternal high blood pressure, acute infections, hard physical work, multiparty, and psychological factors(6).

Globally, Low birthweight has long been used as a good summary measure of public health problem that includes long-term maternal malnutrition, ill health, hard work and poor pregnancy health care Individually it is also a critical determinant for survival in the neonatal period and for future growth and development of the new born, since new born with the low birth weight starts life with a handicap and this may persist in future(7)Birth weight is a powerful predictor of infant growth and survival. Infants born with low birth weights begin life immediately disadvantaged and face extremely poor survival rates.,(8) Malnourished mothers are at increased risk for complications and death during pregnancy and childbirth and their infants are more likely to have low birth weight, fail to grow at a normal rate, and have higher rates of disease and death. (9) Being low birth weight during early development have a profound impact

on one's risk for development of future adult disease. It is, a surrogate marker of poor fetal growth and nutrition, is linked to coronary artery disease, hypertension, obesity, and insulin resistance(10).

1.2 Statement of the problem

Low birth weight is a global challenging public health problem. It is a most significant risk factor for adverse health outcomes including common childhood diseases. The UNICEF-WHO low birthweight estimates indicate that one in seven livebirths – 20.5 million babies globally suffered from low birth weight in 2015(1). Similarly 6.9% from UK and 7% from Germany are born either premature or small for gestational age (SGA)(11).

Low and middle income countries account for a disproportionate burden of Low birth weight in which over 91% of the world's LBW infants are born in Low and middle income countries from this 9.3 million of them in South Asia and 3.1million in sub-Saharan Africa(12).Africa was home to about one quarter of all low birthweight newborns, with the majority born in Eastern and Western Africa, 11 % and 14% respectively (13).

According to Ethiopian demographic health survey(EDHS) 2016 estimates, 13% of them weighed less than 2.5kg at birth.The previous DHS survey revealed that 14% LBW in 2005, 11% in 2011 ,according to mother's report, 16% of births are very small, 10% are smaller than average (14–16).

Low birth weight is the major predictor of infant morbidity and that it contributes substantially to the overall burden of childhood mortality. Being born with LBW is generally recognized as a disadvantage for the infant. Globally Low birth weight contributes to 60% to 80% of all neonatal deaths(17) . In both developed and developing countries, LBW is an important cause of perinatal mortality and both short- and long-term infant and childhood morbidity, Deaths of LBW infants are 30 times more frequent than deaths of newborns of normal birth weight and they are many times more likely to end up with long-term handicapping conditions (18). They are also at higher risk of perinatal death, adulthood stunting that in turn leading to the intergenerational effect of malnutrition in the affected community (19).

In Ethiopia, the prevalence of under-five mortality ranges from 53 to 169 per 1000 live births out of this neonatal mortality which is mainly attributed by LBW accounts the largest portion. In Ethiopia, in 2014, there were 27,243 deaths due to low birth weight accounting 4.53% of the total deaths (20)

Low birth weight has a significant economic burden for the health system and families. It is one of the most important factors for perinatal mortality and morbidity in both developing and developed countries and contributes to several poor health outcomes It is associated with poor neurological and cognitive

development (LBW individuals had lower IQs compared with the normal birth weight group)(21) childhood morbidity, growth impairment, a range of poor health outcomes, and chronic diseases later in life. It is a cause of both short-term and long-term consequences leading to adverse social and economic impacts (22).

According to different studies in different parts of developing and developed countries: socio demographic medical and obstetric factors, nutritional related factors, behavioral related factors, infant and environmental related factors are potential risk factors for occurrence of low birth weight(18–20,23–25).

World Health Assembly set a policy target to reduce LBW by 30% by the end of 2025 with given emphasis on the packages of care provided at the prenatal, ante-natal, intra-natal, and post-natal period interventions to prevent low birth weight, its components(preterm birth and small for gestational age) and their associated morbidity and mortality, with emphasis on community settings.(26)

Similarly, Ethiopia has adopted the WHO recommendations similar strategies have been implementing. Additional to the comprehensive care that is provided for women and newborns from pregnancy to the postnatal period there is also information that provides insights into the health workforce, health policies, health information and community mobilization relevant to preterm birth and low birth weight Support for adequate feeding with breast milk, continuous skin to skin contact, antibiotics, and antenatal corticosteroids(27).

Despite the enormous prevention options and efforts, LBW still remains a formidable public health challenge for the 21st century and more detailed research is needed to illuminate factors affecting LBW. However as far as my knowledge is considered still a little is known about this paradox, only scanty studies have been conducted regarding the maternal nutritional status, food insecurity, dietary practices and the environmental related factors with regard to as a risk with for low birth weight in Ethiopia(25). Therefore The aim of this study is to identify contextual factors associated with food insecurity, maternal nutritional status, MDDS and environmental factors.

CHAPTER TWO

2; LITERATURE REVIEW

LBW is a multifaceted public health problem and a major determinant of mortality, morbidity and disability in neonatal period, infancy and childhood. LBW has a long term impact on health outcomes of adult life with a substantial cost to the health sector and imposes a significant burden on the society due to non-communicable diseases. Further it is an intergenerational problem in which infants with low birth weight, if not intervened adequately, grow up to be undernourished and stunted as children and adolescents and, ultimately, undernourished women of child bearing age who will be undernourished during pregnancy and then will deliver LBW infants. Hence, birth weight is an essential element in the success of national and global efforts to improve child health, and a major target for public health intervention. As a result, birth weight-especially low birth weight and its determinants have become a focal area for clinical and epidemiological investigations worldwide(13). Identifying the determinants of low birth weight is important because of the health risks associated with low birth weight. These factors are related to the infant, the mother or the physical environment and play an important role in determining the infant's birth weight and future health (1). The following are some factors found to be determinant of LBW broadly falls into four categories: socio-demographic and socioeconomic factors, medical and obstetric, and food security and dietary factors, behavioral factors and environmental factors.

Socio demographic and socioeconomic determinants of low birth weight

Socio demographic characteristics such as age of the mother, socio economic status, and educational status of mothers are determinants of low birth weight(13,30). In addition, in most of the countries, increased risk of LBW in newborns born to mothers with certain specific characteristics, such as residing in rural communities, as well as lower wealth status of households in comparison with the rich group(31).

Case control Study conducted in Germany showed that women with a lower secondary school certificate were 2.6 times more likely to have a child with LBW than those with university/ technological college entrance certificate (32).

Systemic review done on risk factors associated with low birth weight in America show Sociodemographic conditions were predictors of LBW. Maternal age as a predisposing factor, since LBW as an outcome is higher in mothers older than 35 and under 20 years of age.. Another factor is regional inequalities in living conditions, especially in access to maternal and child health, contribute to LBW(33).

Study in India demonstrated that age less than 20 year mothers were 3 times LBW than age 20-29 (34) But, maternal baseline characteristics such as level of education, monthly household income, did not have an association with adverse pregnancy outcomes(24).

Case control study in Iran show that sex, living location and mother's age did not differ between the LBW and the control groups (35)Case control Study in Nepal showed that mothers whose age less than 20 years of age were nearly two times more likely to deliver LBW babies compared to mothers of 20-30 age categories. (36).

Matched case control Study conducted in Malaysia Younger mothers had nearly three times the odds to have LBW baby as compared to older mothers (28).

Systemic review of LBW show that the following factors were shown to have a significant association with the risk of having an LBW infant in developing countries: maternal age of 35 to 49 years. Illiteracy, and being in the poorest socioeconomic stratum. Mothers with advanced age (35 to 49 years) had a significantly greater risk of delivering LBW babies than younger mothers Illiterate mothers (no formal education) had a higher risk of delivering LBW babies than more highly educated mothers in Armenia, Indonesia, Jordan, Nepal), Pakistan and Uganda (31).

Study conducted in sub-Saharan countries Mothers aged <16 years showed higher risk for the delivery of a low birth weight infant. In a sub analysis restricted to prim parous women, preterm delivery: low birth weight at delivery very young maternal age (<16 years) was the variable with the highest risk for the delivery of a low birth weight infant, 16%)compared to adult mothers aged 20 to 30 years, 9% (37).

Study in morocco statistical association between the LBW and maternal age (35 years and over). In contrast to other studies Standard of living of families did not have any effect on the LBW.(38).

A review of low birth weight in Ethiopia, Socio-demographic (maternal education level, occupation, income and place of residence are the common risk factors for low birth weight in Ethiopia. Deprived socio-economic status can increase the incidence of LBW. Maternal literacy level, paternal educational status and presence/absence of radio/television in the household were predictors of LBW. low birth weight was more common among children of the youngest mothers, age less than 20 and older mothers, age 35-49 and monthly income <26 United States Dollar (USD), lack of formal education and being merchant were associated with LBW(29)(39).

In contrast to other studies unmatched case control Study in Amhara regional state revealed socio demographic characteristics of the mothers not determinants of LBW. Such as, place of residence, educational status of the mothers have not significantly associated with low birth weight.(40),

Another Facility-based unmatched case-control study conducted among deliveries that took place at Debreberhan Referral Hospital show, mothers of age 15-24 significantly determinant of LBW (41).

Case control study in debremarkos referral hospital shows that monthly income of less than 1500ETB determinant of LBW(42). Similar Studies in Tigray shows Mothers who delivered at the hospital at the age of less than 20 years were 1.7 more likely to deliver LBW babies than mothers aged 20–34 years is significantly associated with LBW (43).

Another study in wolaita sodo revealed that Women who were, housewives had a higher risk of having term low birth weight newborns. In contrast to other studies there is a lesser odds of those from rural settings to have low birth weight newborns as compared to their counter urban equivalents(44).

Recent study in north showa zone, central Ethiopia Mothers with no formal education had two times increased odds of delivering LBW babies than women with formal education. Non-married women had higher odds of giving LBW newborns as compared to married ones(45).

Study in Jimma show that 65 percent of the mothers attending the maternity facilities to be of rural residence. Those mothers residing in urban areas had high proportion of delivering LBW babies compared to rural mothers and the differences were statistically significant. (46).

Case control study in kembata public health facilities this area shows that factors such as urban rural difference, maternal occupational and educational status; religion and marital status of the mothers, were not found statistically associated with term low birth weight. (47).

Medical and obstetric factors

Case control study conducted in Nepal revealed that mothers who had history of premature delivery were five times more likely to deliver as compared to those who do not have history of premature delivery (36). Matched case control design conducted in Malaysia showed that mother with previous history of LBW infants were 3.7 times more likely to deliver LBW infant as compared to their counterparts and mothers who had current hypertension were 4.5 times more likely to deliver LBW baby as compared to those mother who don't have current hypertension(28).

Another Study in china LBW was found to be associated with previous histories of adverse pregnancies, and with pregnancy comorbidities and complications, such as hypertensive disorders during pregnancy, anemia, and gestational diabetes.(48).

Study in India history of previous preterm delivery, gestational hypertension, with LBW. But, other maternal baseline characteristics such as, parity index did not have an association with adverse pregnancy outcomes(LBW)(24).

study in Denmark shows hypertension in LBW mothers was 1.24 compared to those with birth weight >2500 g neonate's mothers.(49).

Systemic review show that factors association with the risk of having a LBW infant in developing countries inadequate antenatal care (ANC), delayed conception, are determinants of LBW. delayed conception (over 48 months) had significant relationship with LBW in Armenia, Cambodia, Colombia, Jordan, Tanzania, and Uganda, In all countries, ANC visits were associated with significant reductions in LBW, while receiving inadequate ANC was associated with an elevated risk of LBW (50).

Study in sub-Saharan countries factors significantly associated with increased risk for low birth weight were country, trimester of first antenatal visit, parity(37).

Study in morocco shows that the risk of LBW was high among women who had over three pregnancies. The maternal morbidities during pregnancy are undeniably associated with LBW (Hypertensive Pregnancy: HP, Anemia). The findings show that the number of the antenatal consultation (ANC) reduces the risk of having LBW. Finally, unwanted pregnancies are significantly associated with LBW. Morbidities during pregnancy, the relationship between spouses contribute to LBW. The number of ANC is a protective factor(38).

Review maternal/obstetric (antenatal care visit, and parity), obstetric and medical disorders during pregnancy (hypertensive disorders of pregnancy,) are the common risk factors for low birth weight in Ethiopia. LBW is highly associated with hypertensive disorders of pregnancy (HDP) because these multi organ disorders can cause intrauterine growth restriction (IUGR). Presence of any medical illnesses, being HIV positive risk factors for LBW. In Ethiopia, different studies showed that, obstetric characteristics of mothers play a role on occurrence of LBW. Prim parity, and lack/infrequent of antenatal care follow-up were factors associated with LBW. Other maternal factors inter-pregnancy interval <2 years were predictors of LBW. Unwanted pregnancy as risk factor for LBW(39).

Case control study conducted Amhara regional state shows that the odds of low birth weight was also higher among mothers who didn't attend ANC as compared to mothers who attended ANC follow up during pregnancy (40).

Facility based case control Study in debretabor shows hospital mode of delivery, maternal history of chronic diabetes mellitus, was found to be independent predictors of low birth weight. On the other hand maternal history of chronic diabetes had preventive effect of low birth weight(41).

Case control study in debremarkos referral hospital shows that Primigavida mothers were about five times more likely to give low LBW than multi parous mothers., Mothers who have hypertensive disorder

during pregnancy were about six times more likely to give LBW baby than those who have no hypertensive disorder of pregnancy Mothers who had three or less visit were about five times more likely to give LBW than who had four and more visits(42).

Study in Dangla shows that women who had previous history of low birth weight had 3.2 times higher odds ratio of delivered low birth weight baby than their counterparts, „So Previous history of low birth weight was independent predictors of low birth weight (51).another Study conducted in Adwa Mothers who wanted the pregnancy were 97% less likely to have LBW babies when compared to those mothers who had unwanted pregnancy. Mothers who had history of abortion were 2.4 times more likely to have LBW babies than those with no history of abortion. Mothers who were reactive for HIV were seven times more likely to have LBW babies than nonreactive mothers(43).

Study in kersa woreda LBW is significantly associated with not attending ANC, (52).

Unmatched case control study in north showa zone show that mothers who had the recommended four or more antenatal care (ANC) visits, those who were not booked had three times increased odds of giving to LBW baby(45).

Nutritional related factors

Case control study conducted in Nepal revealed that mothers lack of consumption of nutritious food during pregnancy increases the risk of delivering low birth baby as compared to those who ate nutritious food during pregnancy (36).

Study in sub-Saharan countries factors significantly associated with increased risk for low birth weight was MUAC(37).

Study in morocco shows that the risk of LBW was high among women with stature less than 150 cm give birth to LBW neonates significantly associated with LBW(38).

Systemic Review about low birth weight in Ethiopia shows that maternal weight and stature, are the common risk factors for low birth weight in Ethiopia. LBW is highly associated with short maternal stature, maternal thinness, Maternal Mid Upper Arm Circumference (MUAC) were factors associated with LBW. Additionally, LBW was significantly associated with anemia during pregnancy Micronutrient and folic acid supplementation during pregnancy were associated with increased birth weight(39).

Case control study conducted Amhara regional state shows The odds of low birth weight was higher among mothers who did not take iron supplementation as compared to mothers who took iron supplementation during the current pregnancy. Mothers who had MUAC below 23 cm(40).

Case control study Debretabour show that hemoglobin levels were found to be the significant predictors of low birth weight. The odds of giving birth of LBW baby were found to be 10 times higher among women with hemoglobin level of < 11 mg/dl compared with counterparts(53).

Case control study in debremarkos referral hospital shows that the proportion of Hgb <11 mg/dl was higher among cases than controls. Mothers with Hgb <11 mg/dl were about three times more likely to give LBW baby than their counter parts and Mothers who had three or less times a day meal were about two and half times more likely to deliver LBW baby than those who had four and above meals per day(40).

Case control Study Dangla shows that women who did not have additional food intake had 5.0 times higher odds ratio of delivered low birth weight neonates than those who had additional food intake during the current pregnancy, additional food intake during the last pregnancy were independent predictors of low birth weight (51).

Study conducted in Adwa revealed that Mothers who had normal hemoglobin status were 98% less likely to give birth to LBW babies than those who had abnormal hemoglobin status and Mothers who took iron with folic acid were 99% less likely to have LBW babies than those who did not take iron and folic acid (43).

Facility based case control study in nekemtie town showed that lack of maternal iron and folic acid supplementation during pregnancy, lack of nutritional counselling during the current pregnancy, not taking snacks, maternal under nutrition(MUAC less than 23cm) and maternal anemia were positively associated with low birthweight.(54).

Study in **kersa woreda** show that LBW was significantly associated with poverty ,maternal Mid Upper Arm Circumference (MUAC) less than 23 cm., longer time to walk to health facility are determinants of low birth weight(52).

study in wolaita shows that not frequently consuming fruits during had a higher risk of having term low birth weight newborns (44).

Unmatched case control study in north showa zone Mothers with no history of nutrition counseling during pregnancy had three times increased odds of giving LBW babies than those who were counseled and Mothers from food insecure households had about four times higher odds of LBW as compared to food secure mothers(45).

Case control study in kembata tembaro zone public health facility shows that those neonates whose mothers didn't have additional food were more than 5 times more likely at risk for term LBW than those neonates' mothers who had additional food during the pregnancy. Regarding iron folate supplementation

during pregnancy, shows that neonates' mothers who didn't receive iron folate were more than eight times at higher risk for term LBW than neonates' mothers who had received iron folate. Mothers from Household food insecurity, Neonates from food insecure households had more than six times higher risk of LBW at term than neonates from food secured households. The mothers who have anemia were more than three times more likely to give low birth weight than non-anemic mothers(47).

Maternal Behavioral related factors

The adverse effects of maternal smoking for human pregnancy are well known. Use of smoking during pregnancy is associated with pregnancy complication and Low birth weight. Maternal smoking reduces mean birth weight by about 150-200 gm and doubles the risk of LBW associated with restriction of intra uterine growth (16).

A systemic review of determinants of LBW highlighted cigarette smoking, alcohol consumption, tobacco chewing were as predictors of LBW in developing countries(55).

Frequency of intake of alcoholic beverages seemed to influence birth weight only in pregnant women who took the drinks on regular basis(56).

Systemic Review about low birth weight in Ethiopia shows that maternal History of khat chewing was associated with low birth weight.(39).

A study conducted in Bale zone Hospitals showed that mothers who had history of Khat chewing were statistically higher at risk to deliver LBW as compared to mothers who didn't chew Khat(57).

Infant related factors

Determinants of LBW in 10 developing countries Female babies were more prone to have a LBW than male babies in Armenia Cambodia ,Colombia Indonesia ,Jordan and Tanzania as well as in all countries overall.(31).

In contrast to other Study in morocco The proportion of LBW in boys (12.37%) and girls (12.21%) showed no significant differences(38).

Fetal factors like infant sex are the common risk factors for low birth weight in Ethiopia. Female sex of a newborn as risk factor for LBW.(39).similarly Unmatched case control study in Amhara regional state the odds of low birth weight was higher among female neonates as compared to their male counterparts.(40).

In contrast to other studies, study conducted in debretabor show that there is no significant association between sex of the new born and LBW (53).

Study conducted in Debreberhan show that Preterm birth) Babies who were born preterm (premature babies) were five times more likely to have low birth weight as compared to those born at their full term (41) another Study conducted in Dangla also shows that pregnant women who delivered before 37 weeks of gestational age had 2.14 times higher odds ratio of delivered LBW neonates than those delivered at term (51).

Study in kembata tembaro public health facilities show that the sex of a newborn being female is more than two times more likely to cause LBW than being male.(58).

Environmental related factors

Various household environmental factors have been implicated in adverse pregnancy outcomes, such as LBW. case control study conducted in bale showed that mothers who use kerosene for cooking were 9 times had low birth weight than mothers who had not use kerosene and mothers who wash hands with water only had 2 times LBW baby than mothers who wash hands with water and soap and mothers who had not having separate kitchen room were 2.6 times had low birth baby than mothers who had separate kitchen(29).

CONCEPTUAL FRAME WORK.

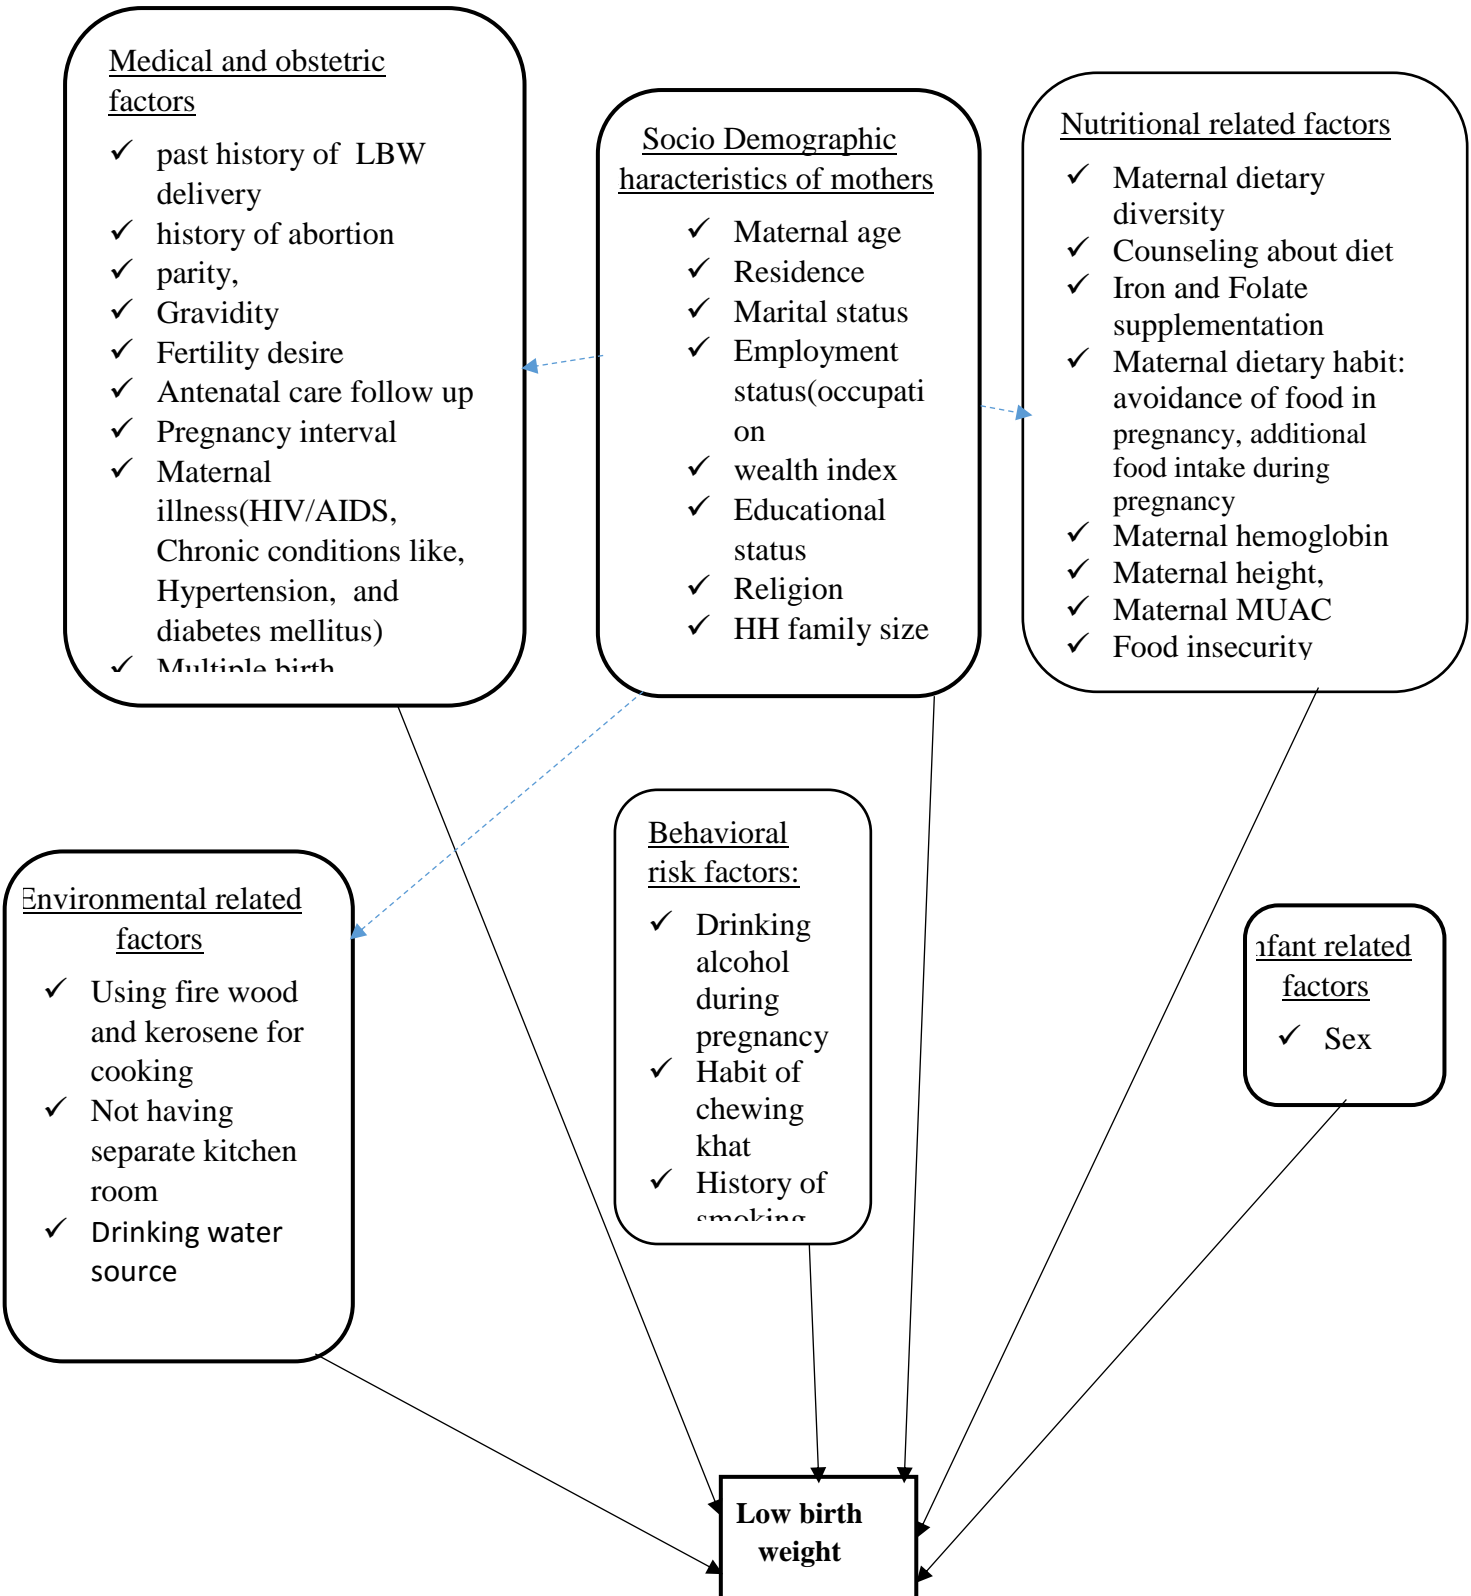

Figure 1 Conceptual framework adapted from literatures to assess determinants of low birth weight among new born in Silte zone, public health facilities, south Ethiopia 2020.

(Endalamaw A et al., 2018; Rajashree K et al., 2015)

1.3 Significance of the study

Birth weight is a good summary measure of multifaceted public health problems that include long-term maternal malnutrition, ill health, and a poor health care during pregnancy and low birth weight. Maternal nutrition has a critical role in the reduction of both maternal morbidity and mortality as well as the new born health status. Women's nutritional status is most vulnerable during pregnancy. Maternal malnutrition becomes a cycle when malnourished mothers give birth to low birth weight infants who in turn become malnourished mothers themselves(28). In spite of the fact that there were many studies on determinants of low birth weight in developing countries, few studies have been conducted regarding the maternal nutritional status and maternal dietary diversity, the environmental related factors with regard to the incidence of low birth weight in Ethiopia(29) no study is done in the study area to the knowledge of the investigator about determinants of low birth weight. Therefore this study aims to fulfill this gap by assessing determinants of low birth weight by using unmatched case control study design, so the finding of this study can help as an input to policy makers (program planner) at different level and NGO working on maternal and child health as well as for health care providers to design appropriate interventions, for ongoing monitoring and analysis of the effectiveness of interventions. In addition it may be helpful in providing information as baseline for future studies. The study may specifically help Silte zone health department, stakeholders and other concerned organizations in the setting to design and take appropriate measures towards the initiation of a suitable nutrition and health promotion programs for pregnant women, which contribute its great share for decreasing the prevalence of LBW neonates.

CHAPTER

3; THREE OBJECTIVE

To identify determinant factors of low birth weight among children, delivered in silte zone public health facilities.

Alternative Hypothesis: -

- The odds of not taking iron folate supplementation are more likely to be among low birth weight neonates' mothers as compared to normal birth weight neonates' mothers.
- The odds of house hold food insecurity status are more likely to be among low birth weight neonates' mothers compared to normal birth weight neonates' mothers.
- The odds of inadequate minimum dietary diversity are more likely to be among low birth weight neonates' mothers as compared to normal birth weight neonates' mothers.

CHAPTER FOUR;

5; METHODS AND MATERIALS

4.1 Study area and period

Silte zone has total population of 1,731,806 from which 949753 females. The reproductive age group were 256721, Expected pregnancies were 76924, under five children 171992. The zone has 224858 households, there are 34 urban and 142 rural health posts with 82 and 163 health extension workers respectively, 37 health centers all gives delivery services and four public hospitals all have Neonatal intensive care unit which admits and treats LBW newborns. The average time takes to reach the health facility is 1 hour and 30 minute. The zone has 30 functional. Regarding to delivery services the zone has achieved 81% skill attendant delivery services (Zone achievements report 2019). The study period was from March 15 to June 16, 2020.

4.2 Study design

Facility based unmatched case control study design was employed

4.3 Source population

All neonates delivered in public health facilities of Silte zone.

4.4 Study population and study unit

Cases: Neonates delivered with low birth weight of $<2500\text{gm}$ in Silte zone public health facilities during the study period.

Controls: Neonates delivered with normal birth weight of $\geq 2500\text{mg}$ in Silte zone public health facilities during the study period.

4.5 Eligibility criteria for cases and controls

4.5.1 Inclusion criteria for cases

For cases: live born singleton baby with birth weight less than 2500gm at birth during the study period

For control: live born, singleton baby with birth weight 2500gm or more at birth during the study period

4.5.2 Exclusion criteria for both cases and controls

Neonates whose mother mentally ill, critically ill/ unable to communicate, placenta previa, abruptio placenta were excluded.

4.6 Sample size determination

The sample size was determined considering a proportional difference approach for case-control study using EpiInfo version 7 statistical software package taking into account the following exposure variables for low birth weight; maternal height, no dietary counseling, no additional food, food insecurity, birth interval, no iron tab given and maternal nutritional status as determined by MUAC.

By using a formula for two population proportions and calculate by Epi info version 7 statistical software package by considering that the percent of controls exposed Height \leq 1.5M among the controls is 6%(main exposure variable)(59). Assuming a 13.1% difference in cases, proportion of cases with exposure becomes 19.1%. Adjusted Odds Ratio of 4.12 to be detected. By considering 95% confidence level, 80% power of the study and control to case ratio of 2:1 is assumed to estimate a required sample size.

Accordingly, after adding 5% for non-response rate 85 cases and 170 controls (a total sample size of 255) were involved in the study.

Table 1 Sample size determination using different exposure variables to study predictors of low birth weight in silte zone public health facilities, southern Ethiopia, 2020

Predictors	CI	OR	Power	Proportion of exposure among case (p ₁)	Proportion of exposure among control (P ₀)	Case	Control	N total	Reference
No iron tab given	95%	2.82	80%	34	15	70	139	209	(40)
No dietary counseling	95%	2.37	80%	74	45	73	146	218	(59)
Food insecurity	95%	6.74	80%	84	38	19	37	56	(47)
No Additional food	95%	5.49	80%	75	27	21	42	63	(47)
Height <1.5m	95%	4.12	80%	15	6	81	161	242	(60)
Birth interval <=2	95%	3.2	80%	49	25	43	86	129	(29)
MUAC ≤ 22cm	95%	2.9	80%	32	12	76	152	228	(59)

4.7 Sampling procedure

Totally there are 41 Public health facilities 4 hospitals and 37 health centers are found in Silte zone which gives delivery service. By taking 30% of the 41 health facilities by simple random sampling technique, 3 hospitals and 10 health centers were selected. Then proportional allocation of newborns to each hospital and health center determined based on the proportion of number of deliveries of one month data last year (data from Megabit 21 to Miazia 20, 2011) in each selected health facilities. The cases and controls were defined according to the birth weight in the labor rooms of the facilities. Consecutive live births of less than 2500 grams in each hospitals and health centers were selected as cases and two normal birth weight babies succeeding each case were selected as controls during the study period.

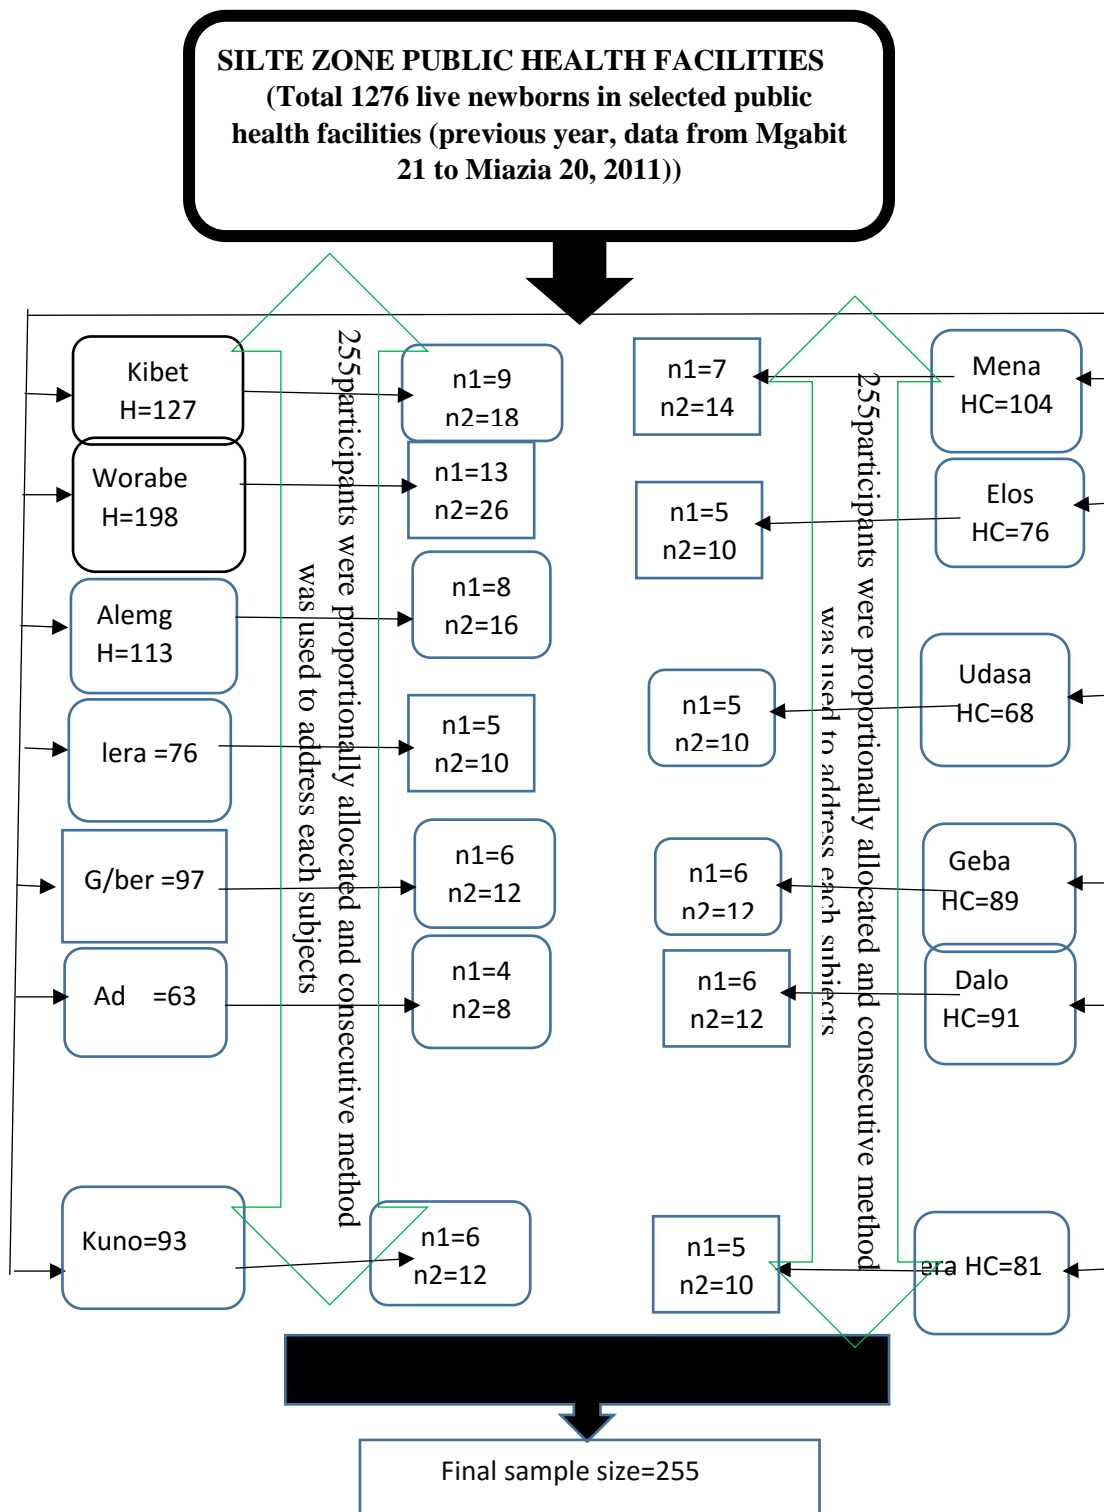

Figure 2; Schematic presentation of sampling procedure, Silte zone public health facilities, South Ethiopia, 2020

4.8 Study variables

4.8.1, Dependent variables

- ✓ Low birth weight

4.8.2, Independent variables

- ✓ Socio demographic and socio-economic factors: maternal age, wealth index, residence, occupation, marital status, education level, religion, house hold size.
- ✓ Medical and obstetrics factors: Gravidity, Parity, Birth interval, pregnancy desire, number of ANC follow up during current pregnancy, history of maternal illness (HIV/AIDS, . hypertension) , bad obstetric history(previous history of low birth weight , history of abortion).
- ✓ Nutritional factors: maternal dietary diversity, food insecurity, maternal MUAC, maternal height, iron and folate supplementation, hemoglobin level, counseling about diet, maternal dietary habit: food preference and food taboo in pregnancy, additional food intake.
- ✓ Behavioral factors: alcohol consumption, khat chewing habit and smoking during pregnancy.
- ✓ Environmental factors: drinking water source, latrine availability, using of kerosene/wood (method of cooking), separate kitchen.
- ✓ Infant factor: infant sex

4.9 Operational and Standard definitions

Low birth weight: - neonate birth weight less than 2,500 gm (up to and including 2,499 gm)(61)

Case: those newborns who have birth weight less than 2500 gm at birth

Control: those newborns whose birth weight greater than or equal to 2500 gm at birth

Gravidity: number of pregnancy (62)

Parity: number of live births (62)

Term baby: a baby delivered after 37 completed weeks and before 42 weeks(62)

Pre term baby: a baby delivered after 28 completed weeks and before 37weeks(62)

Intrauterine growth restriction (IUGR): describe a fetus that has not reached its growth potential because of genetic or environmental factor (63)

Abortion: a fetus born before 28 week of gestation (64)

Alcohol use: those mothers who were drank any type of alcohol at least once per week during the index pregnancy. (61)

Previous history of delivery of LBW: babies were only subjectively assessed from the mothers speaking of “small or very small baby”.

Multiple births: It refers when more than one fetus is carried to term in a single pregnancy (65)

Adequate Minimum Dietary Diversity-Women: - proportion of women who received foods from five or more food groups of the ten food groups(66)

Inadequate Minimum Dietary Diversity-Women: - proportion of women who received foods from five or more food groups of the ten food group). (66)

Additional food: having at least one additional meal than regular due to pregnancy.

Khat use – Khat chewer pregnant woman was defined as pregnant women who chew Khat at least twice a week, for at least one year including the time of current pregnancy(67).

The Wealth Index- is a composite measure of the cumulative living standard of a household. The wealth index was calculated using easy-to-collect data on a household’s ownership of selected assets, such as ownership of television, radio, and materials used for housing construction and types of water access and sanitation facilities. It was generated with a statistical procedure known as principal components analysis; the Wealth Index places individual households on a continuous scale of relative wealth which was categorized in to 3 wealth quintiles(14).

Household food security: exists when all households did not have anxiety and uncertainty about the household's food supply or worried rarely and no problem of insufficient quality and insufficient food intake and its physical consequences(68)

Mild food insecurity: worries about not having enough food sometimes or often, and/or is unable to eat preferred foods, and/or eats a more monotonous Diet than desired and/or some foods considered undesirable, but only rarely(68).

Moderate food insecurity: household sacrifices quality more frequently, by eating a monotonous diet or undesirable foods sometimes or often, and/or has started to cut back on quantity by reducing the size of meals or number of meals, rarely or sometimes(68).

Severe food insecurity: households has graduated to cutting back on meal size or number of meals often, and/or experiences any of the three most severe conditions (running out of food, going to bed hungry, or going a whole day and night without eating), even as infrequently as rarely(68).

Household food insecurity: having anxiety and uncertainty about the household's food supply or worried sometimes or often or households experience problems of insufficient quality of food or insufficient food intake or its physical consequences (68)

4.10, Data collection tools and procedures

Interviewer administered semi structured and pretested questionnaire adapted from different related literatures were used to collect data by face to face interview. The questionnaire was designed to capture the dietary, food security related, iron -folate, behavioral, socioeconomic, environmental, medical and obstetric and infant related factors associated with low birth weight from the participant. Iron and folate supplementation along with history of ANC were asked for each mother. In addition to the questionnaire, hemoglobin level of each mother were taken from the card as hemoglobin is routinely done for each mother receiving delivery service in each public service to determine anemia.

Data were collected by 13 midwiferies and supervised by four health Officers.

Food insecurity

The HFIAS questions were used which is validated for developing country Questions relate to three different domains of food insecurity. i. Anxiety and uncertainty about the household food supply ii. Insufficient quality (includes variety and preferences of the type of food) iii Insufficient food intake and its physical consequences. Each question was asked with a recall period of four weeks (30 days). The respondent were first asked an occurrence question that is, whether the condition in the question happened at all in the past four weeks (yes or no). If the respondent answers “yes” to an occurrence question, a frequency-of-occurrence question were asked to determine whether the condition happened rarely (once or twice), sometimes (three to ten times) or often (more than ten times) in the past four weeks.

Anthropometric Measurements

Anthropometric measurements were done using standardized techniques. Before the real anthropometric data collection, (we took four (4) mothers height and MUAC, four(4) newborn weight and then calculated coefficient variation of height, MUAC and weight were 1.6%, 2.7% and 1% respectively) a standardization exercise was performed during the training to capture technical error of measurement (TEM).

The weight of the newborns was measured within one hour upon delivery using a salter scale (Germany brand). Weight scale was calibrated at 0 with no object on it and placed on level surface before measurement carry out. Every morning and when the instruments move apart, calibration and validation were checked the scales by 2kg metal iron sheet to keep their reliability. The height of mother was

measured using a height board. The height of the mother was measured using standard procedure (bare foot, Frankfurt position, ankle, buttock and shoulder touching the height board) in standing position using height measuring board Stadiometer to the nearest 0.1 cm. The mid-upper arm circumference (MUAC) of the mother was measured right after delivery using flexible non-stretchable standard tape measure in cm. The circumference was measured at the mid-point between the tip of the acromion process of the scapula and olecranon process of the ulna. For left-handed women, the right arm was used instead. Measurement was taken while the arm was hanging down at the side and relaxed to the nearest 0.1cm.

. Dietary Assessment

MDD-W were collected using 24-hour recall method by MDD-W (66). Briefly, the pregnant women were asked to recall the foods they had consumed in the previous 24 h (sunrise to sunrise), first spontaneously followed by probes to ascertain that no meal or snack were left out. A detailed list of all the ingredients of the dishes, snacks, or other foods consumed were generated to enable better classification of mixed dishes. The foods were then categorized into 10 food groups.

4.11 Data quality control

Before data collection the questionnaire was translated by language expert from English version to Amharic language and siltigna language and back translated to English language by different translators to keep the consistency of the questionnaire. Two day training were given prior to actual data collection by the principal investigator to supervisors and data collectors about the objective of the study, how to supervise and collect anthropometric measurement data and the interview questionnaire. The instrument was pretested on 5% of the actual sample in non selected hospital (tora primary hospital) with similar socioeconomic status with the study population before actual data collection and correction were taken accordingly. Weight scale was placed in level surface before measurement was carried out. Every morning and when the instruments move apart, calibration and validation were checked the scales by 2kg metal iron sheet. During data collection questionnaires were checked for completeness on daily basis by data collectors and supervisors.

4.12, Data processing and analysis

After the data collection, the data were checked manually for its completeness every day, edited, coded, entered in to Epi data version 3.1 and finally exported to SPSS version 20 and checked for missing values before analysis. A pregnant women was assigned in the inadequate minimum dietary diversity if the score is <5 and adequate if the score is ≥ 5 . Principal Component Analysis was employed for wealth index and all assumptions like sample size, ratio of variables to cases, the variables included were dichotomous, measure of sampling adequacy (KMO and Anti-Image ≥ 0.5), Bartlett test of sphericity is statistically significant ($P < 0.05$), and no complex structure were seen and explained variation also satisfied.. Frequency distribution were done to check for outliers, inconsistencies and to identify missing values. Descriptive statistics such as frequencies, percentage, summary measures, tables and graphs were used to describe the results of the respondents. Bivariate logistic regression analysis was fitted for each exposure variable with the dependent variable to identify candidates for multivariate logistic regression. Variables with p -value < 0.25 were entered to the multivariate logistic regression. Adjusted odds ratio (AOR) with 95% CI and p value were used to measure strength of association with low birth weight. Variables with P value < 0.05 were declared significant. Moreover, presence of multicollinearity was checked by employing parameter of variance inflation factor (VIF) > 10 . Finally, Model fitness was checked by using Hosmer Lemshow test with p value = 0.518.

4.12 Ethical consideration

Ethical clearance was obtained from research and ethics committee of Jimma university institute of health ethics review board. A support letter was obtained from Silte zone health department. The necessary permission was obtained from each woreda health office, Hospital and health center authorities. Informed verbal consent was obtained from the study participants after explaining the purpose of the study. Coding and aggregate reporting were used to eliminate names and other personal identification of respondents throughout the study process to ensure anonymity, private and confidentiality.

4.13 Dissemination of the finding

The finding of the study may be presented to Jimma University, institute of health, faculty of public health, department of Nutrition and Dietetics. Furthermore, the finding of the study may disseminated for the Silte zone health department, respective woreda health office and respective hospitals and health centers. The findings may also be disseminated to different stakeholders that have a contribution to improve low birth weight. Finally, it may be presented in different symposium & published in reputable journals

Chapter five

Result

5.1 Sociodemographic characteristics

From a total of 255 sample size, 252 mothers of (84 cases and 168 controls) were included in the interviews which made the response rate of 98.8% for both cases and controls. The mean \pm sd of birth weight was 2154.94gm \pm 233.43 for cases and 3022.92gm \pm 311.88 for controls. A higher proportion of newborns were females both in cases and controls that account for 57.1% and 54.8%, respectively. The mean \pm sd of maternal age among the cases was 28.4 \pm 8.6 years and it was 27.72 \pm 6.403 years among controls. The majority, 72.6%, of mothers among the controls and 67.9% among cases were in the age group of 21–35 years. The largest proportion, 96.4% vs. 92.9%, of mothers among cases and controls were Silte, while 98.8% of mothers among cases and 94% among controls were Muslim in religion. About 79.8% of mothers of LBW babies had not formal education and 61.3% among the mothers of normal birth weight (NBW) babies are not formal education. Overall, most of the mothers in both cases and control groups were married (96.4% and 94.6%, respectively). Moreover, 71.4% of mothers among cases and 69.6% among controls were living in rural setting. The higher number of mothers in both case and control group were housewife, (76.2% and 65.5%, respectively) followed by merchant (11.9% and 20.2%, respectively) .regarding to household family size 33.3% among cases and 25.6% among controls have family size of ≥ 5 . A detail of socio-economic and demographic characteristics is presented below in table 2

Table 2; Distribution of socio-economic and demographic characteristics among mothers of LBW case and NBW controls in Silte zone public health facilities, southern Ethiopia, 2020

Variables		Cases no. (%)	Controls no. (%)	Total N (%)
Infant sex	Male	36(42.9)	76 (45.2)	112 (55.6)
	Female	48(57.1)	92 (54.8)	140 (44.4)
Maternal age	≤ 20	15(17.9)	22(13.1)	37(14.7)
	21-35	57(67.9)	122(72.6)	179(71)
	>35	29(14.3)	24(14.3)	36(14.3)
Religion	Muslim	83(98.8)	158(94)	241(95.6)
	Orthodox	1(1.2)	6(3.6)	7(2.8)
	Protestant	-	2(1.2)	2(0.8)
	Others	-	2(1.2)	2(0.8)

Ethnicity	Silte	81(96.4)	156(92.9)	237(94)
	Gurage	3(3.6)	7(4.2)	10(4)
	Hadiya	-	2(1.2)	2(0.8)
	Amhara	-	2(1.2)	2(0.8)
	Oromo	-	1(0.6)	1(0.4)
Residence	Rural	60(71.4)	117(69.6)	177(70.2)
	Urban	24(28.6)	51(30.4)	75(29.8)
Marital status	Married	81(96.4)	159(94.6)	240(95.2)
	Divorced	1(1.2)	4(2.4)	5(2)
	Widowed	2(2.4)	5(3)	7(2.8)
Educational status	Not formal education	67(79.8)	103(61.3)	170(67.5)
	Formal education	17(20.2)	65(38.7)	82(32.5)
Occupation of the mothers	Government employed	5(6)	12(7.1)	17(6.7)
	Private employed	4(4.8)	11(6.5)	15(6)
	Merchant	10(11.9)	34(20.2)	44(17.5)
	Housewife	64(76.2)	110(65.5)	174(69)
	Other	1(1.2)	1(0.6)	2(0.8)
HH family size	>=5	28(33.3)	43(25.6)	71(28.2)
	<5	56(66.7)	125(74.4)	181(71.8)
Wealth index	Lower	45(53.6)	96(57.1)	141(56)
	Middle	31(35.7)	51(30.4)	81(32.1)
	Upper	9(10.7)	21(12.5)	30(11.9)

Medical, obstetric and infant related characteristics

Proportions of antenatal care follow up among cases and controls were 61.9% and 92.3% respectively and 43.1% among cases and 10.6% among control had ANC follow up of <4 times. Mothers who described their pregnancy as unplanned but wanted were 26.2 % and 20.8% among cases and controls, respectively. Maternal chronic hypertensive disease among cases was 2.4% while controls had 3%. Few mothers among cases and controls, reactive for HIV test. History abortion was observed among 20.2% of mothers in cases and 23.8% of mothers in controls. Majority of mothers both in cases and controls were multigravida (73.8% and 69%) respectively. pre term delivery was observed among 13.1% of mothers in cases and 9.5% of controls. Majority of mothers in both cases and controls were multipara which accounts 67.1% and 60.3% respectively. regarding to birth interval 30.6% among cases and 28.4% among controls had birth interval of <=2 years. Mother who chew khat always, usually, sometimes among cases were 9.5%,15.5%,6% respectively and 3.6%,12%, 4% respectively among controls while few mothers both

among cases and control were sometimes drunk alcohol. The distribution of infant, medical and obstetrics characteristics presented in table 3 below.

Table 3; Distribution of infant, medical and obstetrics characteristics among mothers, of LBW cases and NBW controls in Silte zone public health facilities, southern Ethiopia, 2020

Variables	Category	Cases no. (%)	Controls no. (%)	Total N (%)
Gravidity	Primigavida	22(26.2)	52(31)	74(29.4)
	multigravida	62(73.8)	116(69)	178(70.6)

	Sometimes	5(6)	7(4)	12(4.7)
drink alcohol	No	83(98.8)	164(97.6)	247(98)
	Sometimes	1(1.2)	4(2.4)	5(2)

Nutritional and Anthropometric Related Factors

The mean \pm SD of maternal height for cases and controls was 1.588(0.09), 1.63(0.07) meters respectively. Proportion of mothers who did not take additional food in cases were 79.8% while, 38.7% among controls were did not take additional foods during pregnancy. Mothers with a height of less than 150cm were 25% among cases and 4.8% among controls. Undernutrition in mothers as defined by MUAC < 23cm was 26.2% and 10.7% among cases and controls respectively. Mothers who had not received iron and folate supplementation during pregnancy were 36.9% and 9.5% among cases and controls respectively. Mothers who did not counseling about diet were 76.2% and 39.3% among cases and controls respectively. Proportion of maternal hemoglobin <11mg/dl among cases were 33.3% while in controls it was 7.7% The largest proportion of mothers 92.9% among cases and 62.5% of mothers among controls had inadequate MDD-W. A detail of Nutritional and Anthropometric characteristics is presented below in table 4.

Table 4: Nutritional and anthropometric characteristics among mothers, of LBW cases and NBW controls in Silte zone public health facilities, southern Ethiopia, 2020

Variables	category	Cases no. (%)	Controls no. (%)	Total N (%)
Additional food	Yes	17(20.2)	103(61.3)	120(47.6)
	No	67(79.8)	65(38.7)	132(52.4)
Food avoidance	Yes	21(25)	39(23.2)	60(23.8)
	No	63(75)	129(76.8)	192(76.2)
Fasting	Yes	21(25)	39(23.2)	60(23.8)

	No	31(36.9)	11(6.5)	42(16.7)

Environmental related factors

Mothers who delivered low birth weight baby had not separate kitchen, it was around 40.5% and mothers who had not separate kitchen among controls was 44%. Most of the mothers were using firewood for cooking among both cases and controls (65.4% and 60.7%) respectively. Detail of environmental characteristics are presented in table 5.

Table 5; Environmental related characteristics among mothers, of LBW cases and NBW controls in Silte zone public health facilities, southern Ethiopia, 2020.

Determinants of low birth weight

In bivariate logistic regression analyses performed to identify candidate variables for multivariable logistic regression model in identifying determinants of low birth weight, all variables having p-value less than 0.25 were considered for the final multivariable logistic regression model

After entering each explanatory variables in to bivariate analysis, educational status of the mother (not read and write), Household family size ≥ 5 , house hold food in security, Not ANC visits, Not additional food, MDD-W score < 5 , Not Iron folate supplementation during pregnancy, Height of the mother $< 1.5\text{m}$, MUAC of the mothers $< 23\text{cm}$, Not counseling about diet and hemoglobin $< 11\text{g/dl}$ become statically significant with low birth weight at p value < 0.25 in 95%CI.

Multivariate logistic regression

The selected independent covariates with p-value < 0.25 in bivariate logistic regression were entered into the multivariable logistic regression model to isolate the independent predictors of LBW using backward elimination stepwise likelihood ratio method. After entering all Candidate variables in to multivariable analysis only household food insecurity, Hemoglobin of the mother, additional meal during pregnancy, Minimum dietary diversity score of women, Iron supplementation were significantly associated with LBW.

When food secured households Compared to food in secured households, Neonates from food in secured households mother had more than six times at risks of LBW (AOR= 6.853; 95%CI; (3.008, 15.613) than neonates from food secured women. Also those neonates whose mothers hadn't additional

food were more than three times (AOR= 3.096; 95%CI; (1.278, 7.502) more likely at risk for LBW than those neonates' mothers who had additional food during pregnancy. When we see iron folate supplementation during pregnancy neonates' Mothers Who didn't receive Iron folate during pregnancy were more than four times at risk for term LBW than neonates' mothers who had received iron folate. (AOR=4.175; 95%CI (1.437, 12.300). the odds of LBW babies among mothers with inadequate MDD-W were higher than mothers with adequate MDD-W (AOR=4.131(CI ;(1.403, 12.158). Mothers whose hemoglobin less than 11 were 5.213 times more likely to have low birthweight neonate (AOR = 5.213 (CI ;(1.923, 14.130) than mother whose hemoglobin were greater than 11.

Table 10;Determinants of LBW In multivariable logistic regression analysis for newborns delivered in Silte zone public health facilities, southern Ethiopia, 2020.

Chapter six Discussion

The present study revealed that the risk of low birth weight was higher among mothers who didn't receive additional food during current pregnancy as compared to mothers who did receive additional food during current pregnancy. Nutrition and weight management before and during pregnancy has a profound effect on development of infants. This is a critical time for healthy fetal development as infants rely heavily on maternal stores and nutrients for optimal growth and health outcomes in later in life. Mothers should consumed more food (increased food intake compare to preconception period) during pregnancy period this findings were consistent with other similar studies done in Jimma, Kembata, Dangla, Amhara regional state, Nepal.(56,46, 50, 40,36).

Intake of iron and folate supplements during pregnancy had significant association with LBW. Mothers who did not take iron and folate supplementation were more likely to deliver low birth weight babies than mothers who did take iron and folate supplementation during pregnancy. Women can develop iron deficiency anemia from the loss of blood during menstruation and from repeated pregnancies; it can also be caused by lack of iron in the diet. During pregnancy, women may develop anemia because the growing fetus draws upon the mother's iron for the development of red blood cells and other tissues. Intake of iron supplements during pregnancy was also found to have a protective effect with respect to term LBW. Randomized controlled trial in USA shows that iron folate supplementation significantly lower incidence of low-birth-weight infants that is 4% in treatment group 17%; in placebo group, $P = 0.003$ (69). Mothers who took iron with folic acid were 99% less likely to have LBW babies than those who did not take iron and folic acid (43). This finding is inline with a study done in Adwa, Amhara regional state, Kembata, nekemtie (43, 40, 46, and 53).

Mothers having inadequate MDD-W had significantly higher odds of giving birth to LBW babies. Inadequate women dietary diversity during pregnancy independently and significantly affected low birth weight in the study. The consequences of inadequate nutritional intake during pregnancy not only directly affects women's health status, but may also have a negative impact on birth weight and early development. Mothers having inadequate MDD-W had significantly higher odds of giving birth to LBW babies. This finding was consistent with a study done in Oromia region and study done in wolaita, in Ethiopia, in which women in the inadequate MDD-W group had an increased risk of LBW and PTB compared with women in the adequate MDD-W group (15, 44). Similarly, a study from Ghana shows that Women dietary diversity score and dietary patterns were found to be protective against low birth weight (40).However, a recent randomized controlled trial in India reported that an intervention that increased consumption of dairy, fruits, and green leafy vegetables before and during pregnancy

through a specially formulated snack had no effect on birth weight (24). This difference might be due to differences in study population, geographical location and the study design.

The significant association between household food insecurity of the mother was significantly associated with term low birth weight. The odd of term LBW was 6.853 times higher among mothers from food insecure households as compared to secured households with corresponding 95% CI of (3.008,15.613). This finding is in line with a case control study finding in Iran and finding in Kembata Tembaro [35, 46]. This finding is further supported by Prospective cohort study in Pakistan which shows food insecurity in pregnancy is associated with low birth weight in neonates, Food insecure women had a 5.439 times increased risk of delivering a low birth weight neonate (RR=5.439, CI=1.710-17.296, p=0.002(70)). Possible explanation for the significant association between food insecurity and low birth weight may be food insecurity reduces the quality and quantity of food available to mothers, limited diversified food, reducing weight gain and impair the nutritional status of the mother which subsequently reduces weight at birth. Food insecure mothers may often restrict their food and sacrifice their own nutrition in order to protect their children from hunger which in turn impairs the nutritional status of the mother and consequently reduces weight at birth. Other possible explanation may be women from food insecure households may be at risk of depression and stress which are potential determinants of term LBW as documented in some studies.

This study showed that mothers whose hemoglobin <11mg/dl were higher odds to deliver LBW neonates compared to mothers whose hemoglobin ≥11mg/dl. This finding is consistent with other studies done in Nepal, Malaysia, India (28, 34,36) and studies in Ethiopia Adwa, Debre Tabor and Debre Markos(40,43,52) Study conducted in Adwa revealed that Mothers who had normal hemoglobin status were 98% less likely to give birth to LBW babies than those who had abnormal hemoglobin status.

Socio economic and sociodemographic factors such as urban rural difference, Wealth index, Household family size, maternal occupational and educational status; religion and marital status of the mothers were not found statistically associated with term low birth weight

A finding of this study is also in line with studies India, Morocco (24, 38) and different studies Conducted in Ethiopia (40, and 52). In contrary to this, a study finding in Germany, show that women with a lower secondary school certificate were 2.6 times more likely to have a child with LBW than those with university/ technological college entrance certificate (32). Study in Iran Standard of living of families did not have any effect on the LBW.(38). Study in Adwa general hospital shows Mothers who delivered at the hospital at the age of less than 20 years were 1.7 more likely to deliver LBW babies than mothers aged

20–34 years is significantly associated with LBW (43). These differences may be due to sample size, Geographical location or study methods followed.

In this Study maternal illnesses (HIV/AIDS, hypertension, UTI), maternal behavioral factors were not significantly associated with term LBW .Which is not in line with different studies. Such as; maternal exposure to Hypertension, urinary tract infection and HIV/AIDS during pregnancy were also reported as risk factor for low birth weight (24,28,36,38, 48) This difference may be owing to the fewer number of cases and controls exposed as observed in the result section. This sample may be insufficient to detect the existing exposure difference between cases and controls which in turn result insignificant association between medical factors with term LBW.

Strength and limitation of the study

The present study has strength; taking new born weight within one hour of delivery can be considered as a major strengths of this study..

However the study has limitations: private health facilities were not included in this study. The completed gestational age was taken from verbal response of respondents. There might be recall bias as respondents had to remember their last date of menstruation. There might be chances of recall bias as this study sought some data based on respondents past history like dietary diversity, number of ANC visit, number of iron tablet taken.But, efforts were made to minimize these biases by remmemebering mothers to recall last menstrual period by local calender method.

Chapter seven

Conclusion

Not taking additional diet during pregnancy, no iron folate supplementation, no dietary diversity, house hold food insecurity and hemoglobin of <11 mg/dl were significantly associated with term Low birth weight. Therefore, the key elements iron intake, additional food, dietary diversity which are likely to improve low birth weight need to be addressed in this study setup. It was also found that low birth weight at term was strongly associated with house hold food insecurity.

Generally, this Implies that low birth weight remains global challenging public health problem.

7.2; Recommendations

For health facilities

- Identification of women at risk of malnutrition (such as poor and food insecure women)

Provision of nutritional support (in the form of food supplements, micronutrient Supplements) during pregnancy.

- Health service providers should focus on health information related to nutrition diversification and balanced diet.
- Provision of daily iron intake and reinforcing women not to withdraw the recommended iron intake.
- Regular assessment of Iron-Folate adherence

For government officials and policy makers

- Design strategies to decrease household food insecurity and supplementation of additional food for food insecure pregnant mothers.
- Strengthening interventions on intergenerational malnutrition

For researchers

- ❖ Additional research such as large scale (community based with large sample size), strong designed study (prospective cohort or experimental study) including depression status of the mother need to be conducted

Annexes

Annex1: English Version Questionnaire

Jimma University, Institute Of Health, Faculty of Public Health, Department Of Nutrition and Dietetics

Hello! My name is..... I am here on behalf of: Shafi Seid student of Jimma University, Institute of Health, Department of Human Nutrition and Dietetics. he is conducting a research for the Partial fulfillment of second degree on „Determinants of LBW among delivered child in silte zone public health facilities, southern Ethiopian“ “The information you provide will help to indicate potential intervention points for stakeholders by identifying major risk factors of LBW. Your name will not be recorded in any part of the questionnaire in order to ensure confidentiality of the information you provide. The study doesn’t have any harm to the study mothers and to their child. You may ask us to clarify questions if you do not understand them or can stop the interview at any time.

Are you willing to participate in this study? No (say thank you) Yes (continue interviewing)

To be completed by the interviewer

I certify that I have read the above consent procedure to the participant.

Signed: _____

Name of health facility.....

Name of interviewer_____

signature_____

Name of supervisor _____

signature_____ Date

of interview (Ethiopian calendar) ____/____/_____

Part A: Socio-demographic and socio-economic characteristics of the mother

Q.no.	Questions	Choices for response	Skip
A01	Questionnaire with name of health facility & ID Number of study subjects (to be numbered before interview)	Name of Health Facility_____ Mather's full name_____ ID Number a newborn _____ _____ Kebele_____ _____ Zone_____ _____ Gote_____ _____	
A02	Age of the mother	Age in years_____	
A043	Religion of the mother	1. Muslim 2. Orthodox 3. Protestant 4. Other	
A04	Ethnicity of the mother	1. Silte 2. Amhara 3. Oromo 4. Gurage 5. Other	
A05	Educational status of the mother	1. Not read and write 2. Read and write only 3. Primary education 4. Secondary school 5. Collage and above	

A06	Educational status of husband	1. Not Read and Write 2. Read and Write only 3. Primary education 4. Secondary school 5. Collage and above	
A07	Residence of the mother?	1. Rural 2. Urban	
A08	Current marital status of the mother	1. Married 2. Single 3. Divorced 4. Widowed	
A09	Current occupation of the mother	1. Student 2. Government employed 3. Private employee 4. Merchant 5. House wife 6. Day laborer 7. Farmer 8. Others (Specify)	
A10	Current occupation of husband	1. Student 2. Government employed 3. Private employee 4. Merchant 5. Farmer 6. Day laborer 7. Others (Specify)	
A11	Your household family size	Number_____	
A12	Head of your household	Wife01 Husband02	
A13	Matrimonial status of husband	Monogamist.....01 Polygamist.....02	

Part B: wealth index

Now I will ask you about some fixed assets that your household has.

Q.no.	Questions	Yes	No
	Does the household have any of the following properties? (Circle)		
B01	Has household access to electricity?	1	0
B02	Functioning Television	1	0
B03	Watch/clock	1	0

B04	Refrigerator	1	0
B05	Radio	1	0
B06	Mobile telephone	1	0
B07	Non-mobile telephone	1	0
B08	Table	1	0
B09	Chair	1	0
B10	Bed with cotton/sponge/spring mattress	1	0
B11	Electric mitad	1	0
B12	Kerosene lamp/pressure lamp	1	0
B13	Bicycle	1	0
B14	Motor cycle/ Bajaj	1	0
B15	Car	1	0
B16	Animal-drawn cart	1	0
B17	Tanker truck	1	0
B18	Cart with small tank	1	0
B19	Water pump	1	0
B20	Piped water	1	0
B21	Piped into dwelling	1	0
B22	Piped to yard/plot	1	0
B23	Public tap/standpipe	1	0
B24	Borehole	1	0
B25	Dug well	1	0
B25	Water from spring	1	0
B27	Rainfall water	1	0
B28	Surface water	1	0
B29	River/Lake/Pond/Stream/Dam	1	0
B30	Bottled water	1	0
B31	Has household toilet facility?	1	0
B32	Do you share this toilet facility with other households?	1	0
B33	Does any member of this household own any agricultural land?	1	0

B34	Does any member of this household have a bank or microfinance saving account?	1	0
	Does the household have any of the following animals? (Circle)	yes	No
B35	Oxen	1	0
B36	Cows	1	0
B37	Horse/mules	1	0
B38	Goats/Sheep	1	0
B39	Chickens	1	0
B40	Donkey	1	0

Part C: New born characteristics

Q.no.	Questions	Choices for response	
C01	Sex of the newborn?	Male _____ 1 Female _____ 2	
C02	Gestational age of the new born	1, greater than 37 weeks 2, less than 37 weeks	
C03	Birth length of the newborn?	Birth length in cm: L1_____L2.____L3_____	
C04	Birth order of the newborn	Number_____	

Part D: Maternal medical and obstetrics factors

Q.no.	Questions	Choices for response	Skip
D01	What is gravidity of the mother?	Gravidity: _____	
D02	What is parity of the mother? That is any delivery that passed 28 weeks of gestation.	Parity: _____	If she was Gravida-I skip to D03
D03	Was there any history of abortion?	1. Yes 2. No 3. Don't know	If answer is "No" skip to QD05
D04	Total number of abortion	
D05	Was there any history of preterm delivery (≤ 37 wk)?	1. Yes 2. No 3. Don't know	
D06	When did your last menstrual period starts? (Gestational age)	Gestational age at delivery in weeks: _____	
D07	Birth interval(if any preceding birth)	-----	
D08	What type of pregnancy is it?	1. Planned and wanted 2. Unplanned but wanted 3. unplanned and unwanted	

D09	Have you ever attended ANC follow up for your current delivery?	1. Yes 2. No 3. Don't know	
D10	At what months of the current pregnancy you started ANC?	At _____ months	
D11	How many times did you have ANC visit for the current pregnancy?	In number-----	
D12	During this pregnancy, did you receive any multivitamin tablets or syrups? (Show tablets and syrup). Ask to see the tablets and syrups.	1. Yes 2. No 3. Don't know	
D13	During this pregnancy or any time, were you given an injection in the arm to prevent the baby from getting tetanus that is convulsion after birth?	1. Yes 2. No 3. Don't know	
D15	During this pregnancy, did you take any drug for intestinal worms?[show mebendazole tablets and syrup]	1. Yes 2. No 3. Don't know	
D17	Do you have any chronic medical illness?	1. Yes 2. No 3. Don't know	
D18	Which chronic medical illness (more than one response is possible)	1. Chronic hypertension 2. Diabetes mellitus 3. Pregnancy induced hypertension 4. Others (Specify)	
D19	During your current pregnancy, have you been told that you have developed gestational diabetes mellitus?	1. Yes 2. No 3. Don't know	
D20	During this pregnancy, have you been told that you have developed pregnancy induced hypertension?	1. Yes 2. No 3. Don't know	
D21	HIV status of the mother(PICT)	1. Reactive 2. Non-reactive 3. Don't know	

Part E: Minimum Dietary Diversity-Women

READ OUT THE LIST Circle “1” for mentioned and “0” for not mentioned Food categories		Coding	
E01	Any food made from grains (sorghum, maize, wheat, teff, millet,).....	1	0
E02	Any other food made from roots or tubers? (potato, sweet potato, cassava, or other local roots or tubers).....	1	0
E03	Any food made from pulses (e.g. lentils, beans, soybeans, or peas).....	1	0
E04	Any food made from nuts (e.g. peanut butter, peanuts).....	1	0
E05	Any food made with oil, fat or butter...	1	0
E06	Any dairy product (e.g. milk, cheese or yoghurt).....	1	0
E07	Meat (e.g. lamb, beef, veal, goat , liver, brain, all other organ meats like tripe, Offal).....	1	0
E08	Poultry (e.g. chicken, turkey, duck).....	1	0
E09	Fish	1	0
E10	Eggs.....	1	0
E11	Dark green leafy vegetables (Swiss chard, kale, lettuce, spinach).....	1	0
E12	Any food made from pumpkins, carrots, cabbage, red sweet potatoes, mango, papaya, bell paper, green	1	0

E13	Any other fruits? (e.g., bananas, apples, avocados, fig, grapes, guava, orange, lime.....)	1	0
E14	Any other vegetables? (E.g. onion, tomatoes, garlic)	1	0

Part F: Maternal dietary habit

Know I would like to ask you about the habit of your diet during the current pregnancy

Q.no.	Questions	Choices for response	Skip
F01	During the current pregnancy, how many meals do you usually eat within a day?	1. Once 2. Twice 3. Thrice 4. Four times 5. Five times and above	
F02	Have you taken additional food than usual during the current pregnancy?	1. Yes 2. No 3. Don't know	
F03	During the current pregnancy, what is your most typical meal pattern within a day?	1. Breakfast- lunch- dinner 2. Breakfast-snack - lunch- dinner 3. Breakfast- lunch-snack- dinner 4. Breakfast-snack- lunch-snack- dinner 5. Breakfast-snack- lunch-snack- dinner- late night snack	
F04	What was your meal frequency within a day before this pregnancy?	_____ Times.	
F05	During the current pregnancy, did you have any habit of skipping meal?	1. Yes 2. No 3. Don't know	If answer is "No/don't know" skip to Q.F07.
F06	If yes to # Q05, what is/are your reason/s to skip your meal?	1. Tiredness 2. Busy at work so I forget 3. Not to increase weight 4. Other (specify)	
F07	Do you fast while you are pregnant?	1. Yes 2. No 3. Don't know	
F08	Is there any food item that you avoided after you became pregnant	1. Yes 2. No 3. Don't know	If answer is "No/don't know" skip to part F13

F09	If yes to # Q09, which food item did you avoid most?	<ol style="list-style-type: none"> 1. Coffee 2. Porridge, “atmit”, bread, linseed 3. “Shirowot”(other legumes) 4. Key sir, tomato, chilly (other vegetables) 5. Egg, milk and milk products 6. Banana or other fruits 7. Meat 8. Other(specify) _____ 	
F10	What is/are your reason/s to avoid the above mentioned food item/s?	<ol style="list-style-type: none"> 1. Personal dislike (aversion) 2. not allowed to pregnant women to eat(cultural belief) 3. Religion 4. other, specify 	
F11	If personal dislike, what do you think for your dislike?	<ol style="list-style-type: none"> 1. Smell/taste of food _____ is/are the reason/s 2. Heart burn/discomfort 3. Feeling of nausea/vomiting 4. I don’t know the reason 	
F12	If cultural belief, what cultural reason/s make the above food items difficult forbidden to eat?	<ol style="list-style-type: none"> 1. Will make baby big &labour 2. Will be plastered on fetal head and body 3. Fear of abortion 4. Evil eye 5. Fetal abnormality 6. Other, specify 	
F13	In the last nine months, how often did you eat meals outside of your home?	<ol style="list-style-type: none"> 1. Per day 2. Per week 3. Per month 4. Never 5. Other, specify 	
F14	Did you get Counseling about diet During ANC follow up?	<ol style="list-style-type: none"> 1. Yes 2. No 	

Part G. Behavioral risk factors

Q.no.	Questions	Choices for response	Skip
G01	During your current pregnancy, have you ever chew Khat?	<ol style="list-style-type: none"> 1. Yes 2. No 	

G02	If yes, how frequently you were chewing Khat?	1. Always 2. Usually 3. Some times	
G03	During your current pregnancy, have you ever smoked?	1. Yes 2. No	
G04	If yes, how frequently you were smoking?	1. Always 2. Usually 3. Some times	
G05	During your current pregnancy, have you ever drunk alcohol?	1. Yes 2. No	
G06	If yes, how frequently you were drinking alcohol?	1. Always 2. Usually 3. Some times	

Part H. Environmental factors

Know I would like to ask you about the sources of water and availability of latrine for your household members.

Q.no.	Questions	Choices for response	Skip
H01	What is the main source of drinking water for your household members? Source of drinking water	Piped into dwelling01 Public tap/standpipe.....02 Tube well/borehole.....03 Tanker-truck.....04 Surface water (river, lake, pond, and irrigation channel.....05 Other (specify)_____ 77	
H02	How long does it take to fetch water? That means get water and come back to your home?	Less than an hour..... 01 One hour or more.....02 Water on premises.....03	
H03	Do you treat your water in any way to make it safer to drink? (Do not include washing water container)	No.....00 Yes, always.....01 Yes, sometimes.....02	
H04	What do you usually do to the water to make it safer to drink? Anything else? (More than one answer is possible)	No.....00 Boil.....01 Add bleach/chlorine/wuha agar.....02 Strain it through a cloth.....03 Use water filter (sand, composite, etc).04 Let it stand and settle.....05 Water purifying product.....06 Other (specify).....77	

H05	What kind of toilet facility do members of your household usually use?	Flush to piped sewer system.....01 Flush to septic tank02 Flush to pit/latrine.....03 Flush to somewhere else.....04 Ventilated improved pit/latrine (VIP)...05 Pit/latrine with slap.....06 Pit/latrine without slap/open pit07 Composting toilet.....08 No facility/bush (field).....09 Other (specify).... 77 Don't know88	
H06	How does your household primarily dispose of household waste?	Collected by municipality.....01 Buried.....02 Collected by private establishment.....03 Dumped in street/open space.....04 Disposed in the compound.....05 Dumped in river.....06 Burned.....07 Other (specify).....77	
H07	Do you wash your hands after coming from the toilet?	No00 Yes, usually.....;.....01 Yes, sometimes02	
H08	If yes, what do you use when you wash your hands after coming from the toilet? (more than one answer is possible)	Soap.....01 Ash.....02 Plant.....03 None.....04 Other, specify.....77	
H09	Have you separate kitchen?	No.....0 Yes.....1	
H10	What do you use for cooking?	1, Electric 2,kerosene 3,Using fire wood 4,other	

Part I Food insecurity questions

I	Food insecurity condition	Response	code	skip
I01	In the past four weeks, did you worry that your household would not have enough food? Probe: By “household” we mean those of you that sleep under the same roof and take meals together at least four days a week.	Yes No	1 2	If 2
I02	If yes How often did this happen?	Rarely (Once or twice in the past four weeks) Sometimes (3 to 10 times in the past four weeks) Often (more than 10 times in the past four weeks)	1 2 3	
I03	In the past four weeks, were you or any household member not able to eat the kinds of foods you/he/she preferred because of a lack of resources ? Probe: By “ kinds of foods you preferred ” we mean foods that food secure people eat that food insecure people cannot afford to eat. E.g. Eggs, Meat, fish, “Doro wot”, etc. By “ lack of resources ” we mean not having money or the ability to grow or trade for the food	Yes No	1 2	If 2 to I05

I04	If yes How often did this happen?	Rarely (Once or twice in the past four weeks) Sometimes (3 to 10 times in the past four weeks) Often (more than 10 times in the past four weeks)	1 2 3	
I05	In the past four weeks, did you or any household member have to eat a limited variety of foods due to a lack of resources? Probe: When we say “ limited variety of foods ”, we want to mean an undesired monotonous diet for an extended period of days	Yes No	1 2	If 2 to I07
I06	If yes How often did this happen?	Rarely (Once or twice in the past four weeks) Sometimes (3 to 10 times in the past four weeks) Often (more than 10 times in the past four weeks)	1 2 3	
I07	In the past four weeks, did you or any household member have to eat some foods that you really did not want to eat because of a lack of resources to obtain other types of food? Probe: Foods that you really did not want to eat is Food that is considered to be undesirable or socially unacceptable.	Yes No	1 2	If 2 I09
I08	If yes How often did this happen?	Rarely (Once or twice in the past four weeks) Sometimes (3 to 10 times in the past four weeks) Often (more than 10 times in the past four weeks)	1 2 3	

I09	In the past four weeks, did you or any household member have to eat a smaller meal than you felt you needed because there was not enough food? Probe: By “ meal ” we mean the major eating occasions (not including snacks).	Yes No	1 2	
-----	--	-----------	--------	--

I10	If yes How often did this happen?	Rarely (Once or twice in the past four weeks) Sometimes (3 to 10 times in the past four weeks) Often (more than 10 times in the past four weeks)	1 2 3	
I11	In the past four weeks, did you or any other household member have to eat fewer meals in a day because there was not enough food? Probe: “ fewer meals in a day ” than the social norm, eat fewer than three meals in a day.	Yes No	1 2	
I12	If yes How often did this happen?	Rarely Sometimes often	1 2 3	
I13	In the past four weeks, was there ever no food to eat of any kind in your household because of lack of resources to get food?	Yes No	1 2	
I14	If yes How often did this happen?	Rarely Sometimes often	1 2 3	
I15	In the past four weeks, did you or any household member go to sleep at night hungry because there was not enough food?	Yes No	1 2	
I16	If yes How often did this happen?	Rarely Sometimes often	1 2 3	

I17	In the past four weeks, did you or any household member go a whole day and night without eating anything because there was not enough food?	Yes No	1 2	
I18	If yes How often did this happen?	Rarely Sometimes often	1 2 3	

Part J; Iron folate supplementation questions

Q.no	6.Iron folate supplementation	responses	code	skip
J01	During this pregnancy, were you given or did you buy any iron tablets Probe by telling the color of iron or by showing iron tablet	Yes No	1 2	If 2
J02	When did you receive the first tablets	1 st Trimester 2 nd Trimester 3 rd trimester	1 2 3	
J03	For how long did you take the supplement?	One month Two months Three months More than three months	1 2 3 4	
J05	How did you take your supplement?	On daily base..... Weekly..... When I think am sick.--- Other(specify	1 2 3 4	
J06	How many tablets did you collect per visit?	30 table..... 60 table..... 90 table...., >90 table..... Other (specify).....	1 2 3 4 5	
J07	How many tablets per a week you receive	Seven days 4-7 days <4 days	1 2 3	
J08	Is there any health education about iron/folate supplement during collecting your supplement?	Yes No	1 2	
J09	If yes ,what was the issue	Purpose of supplement..... Duration of the supply Side effect ... Follow up visit.....	1 2 3 '	

Part II. Maternal and Newborn anthropometric measurement

I01	Maternal MUAC in cm	In cm-----	
I02	Maternal Height in meter	In meter-----	
I03	Maternal Hgb before delivery(during labor)	In mg/dl-----	
104	Weight of the New born	In k.g-----	

Thank you!
