Title: FINITE ELEMENT ANALYSIS OF REINFORCED CONCRETE BEAM SUBJECTED TO FIRE

A thesis submitted to Jimma Institute of technology, School of graduate studies in partial fulfillment of the requirements for the Degree of Masters of Science in Structural Engineering.

By: LIDETA TEWACHEWU

Main Advisor: ELMER C. AGON (ASSO PROF.) Co-Advisor: HAYMANOT G/SELASE (M.SC)

> November 18, 2019 Jimma, Ethiopia

Declaration

I hereby declare that this thesis entitled "FINITE ELEMENT ANALYSIS OF REINFORCED CONCRETE BEAM SUBJECTED TO FIRE" is my original work which has not been submitted before. This thesis has not been presented in any other university and is not concurrently submitted in candidature of any other degree, and that all sources of material used for the thesis have been duly acknowledged.

Acknowledgment

My first and foremost gratitude goes to Almighty God who is there for me always through the times of trouble and good times.

Completion of this thesis would not be possible without my husband Henok I wish to express my sincere gratitude.

I would like to thank my main advisor, Asso. Prof Elmer C.Agon and co-advisor, Eng.r Haymanot G/selase for their valuable advice and guidance. I would like to express my gratitude to my families and friends for their unrelenting and rigorous moral support not only on my educational careers but throughout my life. Finally, my special thanks go to Jimma Institute of Technology for facilitating this program which helps me for upgrading my profession.

Abstract

Reinforced concrete structure is the common structural system used in Ethiopia and nearly all over the world. Fire represents one of the most severe environmental conditions to which structures may be subjected, and hence, the provision of appropriate fire safety measures for structural members is an important aspect of design. Reinforced concrete (RC) structural systems are quite frequently used in high-rise buildings due to the high structural performance such as strength and durability that it can provide, compared to other materials. Much of the current knowledge on fire behavior of RC members is based on fire resistance tests under standard fire scenarios. There have been no studies under realistic (design) fire scenarios. And thus, there is limitation reliable experimental data, mathematical models or design specifications for predicting the fire performance of RC beams under design fire scenarios.

The objective of this study was to analysis the behavior of RC beam subjected to fire in Ethiopia there is no sufficient experimental and laboratory equipment because of this ,there is no enough and detailed explanation under Ethiopian building code. Therefore, the fire resistance of RC members is an important issue that needs to be considered in the design of RC buildings.

This thesis presents investigate the behavior of reinforced concrete beam subjected to fire by using 3D finite element analysis. The first step was Simulate the structural behaviour of the same beam subjected to mechanical load and nodal temperature (as nodal temperature time history) calculated from the first step. Then, the FE models are computed with existing test data from literature to examine the accuracy of the simulations.

Values from the test and FE model are observed to be close to each other. There are three parameters to analysis the effect of RC beam subjected to fire in this paper which is concrete cover, temperature and duration of time. Results from the analysis indicated that as fire exposure time increases the material behavior degrades. Since the nodal temperature distribution increases with an increase in exposure time. When the concrete cover is zero, the stress along the center of the beam highly decrease and when the concrete cover is thirty, the stress along the center of the beam highly increases. When the temperature and duration of time increase, the vertical deflection at mid span increase.

 $Key \ Words$: finite element model, reinforced concrete beam, heat transfer, fire

Chapter 1

Introduction

1.1 Background of the study

Fire accident is one of the dangerous accidents that could happen to any service structure in unexpected time. in our country, there were so many lives taken and damaging fire accident caused on Taitu Hotel. Anwar mosque and in recent time there is an accident in Bahirdar town and there was loss of human life and failure of structure .Reinforced concrete (RC) structural systems are quite frequently used in high-rise building and other built infrastructure due to a number of advantages they provide over other materials when used in building .The provision of appropriate fire safety measures for structural members is an important aspect of design. Since, fire represents one of the most severe environmental condition to which structure may be subjected in their life time. Fire is an accident which could occur in two ways, the first one is by means of human beings faults and the second is through natural disaster. Mostly fire occur in the daily activities of human being. In case of this there is loss of human life and property is occurs in Ethiopia and in the world. So the objective of fire safety is to protect human life and property. Fires occur at any time in building. Because of this the safety of occupants and maintaining the integrity of the structure are major importance, in the design of structure Building codes . requirements for fire resistance are sometimes overlooked and this may lead to costly mistake [18].code based structural fir safety requirements refers to fire resistance which is defined as the ability of structural element to maintain its load-bearing function under standard fire condition [20]. The fire resistance rating of structural member is the elapsed time it exhibits resistance with respect to structural integrity, stability, and temperature transmission while exposed to standard fire condition [3]. The measured fire resistance of a structural member or assembly is dependent on the geometry of elements, materials used in construction, load intensity fire exposure, and the characteristic of a given heater |15|. In general for safe design fire consideration must be part of preliminary design stage.

Figure 1.1: The Windsor Tower in Madrid after 26 hour in 2005[18]

1.2 Statement of the problem

Now a days many buildings around the world collapsed due to fire, Because of this, a loss human life and money were occurring in each of the year. But still there is no sufficient research on buildings subjected to fire. In Ethiopia building code, the previous 1995 and new building code under no detailed and enough provision existing about the performance of different kinds of construction material for fire. But due to growth of infrastructure, increasing interest of safety in this country, repetitive analysis and studies on fire resistance property determination of different construction material and structural member must be given high value. Sustainability of structures is a vital issue in the construction industry. Exposure to fire or elevated temperature is serious condition that leads to change in materials properties. Consequently, change in overall behavior is expected. Hence, building should be provided with sufficient structural fire resistance to with stands in such circumstance, or at least give occupants to scape before strength and, or stability failure occurred. In structural design of buildings in addition to normal gravity and lateral loads it is necessary to design the structure to safely resist exposure to fire. However, it is usually necessary to guard against structural collapse for a given period of fire exposure. This paper tried to consider the effect of different concrete cover with different temperature and exposure time using finite element analysis.

1.3 Objectives of the research

1.3.1 General Objective

The main objective of this research was to analyze reinforced concrete beam subjected to fire using Finite Element Analysis.

1.3.2 Specific objective

The specific objectives of this research are:

- Validate the experimental result by using finite element.
- To evaluate temperature effects at critical nodes of the beam.
- To evaluate the effect of concrete cover with different temperature and duration of time.
- To identify the effect of fire on thermal properties of reinforced concrete beam at different exposure time.

1.4 Significance of the Study

The study add knowledge on understanding the analysis of fire response of concrete beams using finite element method and the result obtained from this study is helpful for further study and coming researcher The old EBCS as well as the new EBC does not discuss about fire design of concrete structure deeply, but fire is the most severe environmental condition like earthquake and wind load subjected to building structures in their lifetime. Exposure to fire or elevated temperature is an extreme condition that leads to change in materials properties; consequently, change in overall is expected. Therefore, this study will add valuable information on the behavior of concrete beam under fire to fill this gap. This study used to design reinforced concrete beam for fire and model, to assess the capacity of the beam after fire, Generally this paper helps practical guidelines for fire resistance design of reinforced concrete beam under building code.

1.5 Scope of the thesis

This study shall cover the effect of concrete cover with different duration of time and temperature to analysis the behaviour of RC beam subjected to fire.

1.6 Organization of the Thesis

The research is organized in to five chapters. The first chapter is stated about the general background, objectives, significant of the study and scope of the study. The second chapter describes previous works done about the effect of fire on the capacity of reinforced concrete beam. The third chapter is the main body of the research, which consists of the methodology used, and the procedures followed in conducting the research. The fourth chapter consists of discussion and verification of the obtained result and finally the fifth chapter provides conclusion and recommendations of the research.

Chapter 2

Literature Review

2.1 Introduction

Reinforced concrete is one of most commonly used construction materials due to its excellent properties including good fire resistance. However, concrete resistance to fire should not be taken for granted. The measure used to assess the performance of building in structure on fire is started in the early 1918. Fire analysis applied in either in laboratory or finite element method, But experimental approach is expensive for the country like Ethiopia. the equipment to asses behavior of structural element is not available in developing country. That is why EBCS code also have not detailed explanation regarding fire design. But finite element analysis more preferable than either analytic or experimental approach analysis and finite element analysis also consider some variables which is difficult to undertake in the laboratory.

2.2 Partition work

Researchers has been working on the performance of structural building element on fire on different time. One of the paper [16] his doing in the laboratory by changing concrete cover and his research shows that spalling of failure concrete started around 100 degree Celsius and he said that the contribution of concrete cover to reinforcement in fire resistance of beam is not clearly observed .concrete surface temperature rise to higher level reduces compressive strength of concrete and residual shear strength of RCB [5]. Yet this paper the beginning concrete cover is one the protection of fire, safe transmission bond force and durability so he is not address the main objective of the paper. In [20] also do the performance of RC beam in finite element, and the model is to applied by five parametric study namely degree of axial restraint, span to depth ratio, fire scenario, load level and failure criteria on the fire response of restrained RC beam. this paper showed that the fire induced restraint has negative effect on fire resistance of slender beams having high span-to-depth ratio [16]. This paper presents a numerical procedure for predicting the mechanical behavior of RC beam exposed to fire. Using a two dimensional finite element analysis [18] also model the load-displacement behavior of RC beam of different configuration and multidimensional data analysis technique is used.

In [13] this paper is address the effect of burning by fire flame on the behavior and load carrying capacity of rectangular reinforced concrete beam. And the paper take to dependent variable which are RC beam rectangular are cast and cooled in two ways cooled in water and cooled in water and get result which is reduced in (2-5%) cooled in water than cooled in air.

In [7], the paper states that complex behavior of structure in fire. In [3], the paper also address the effect of fire induced restraint on the fire response of RC beam in finite element.

In [19] the paper use non-linear analytic methods to determine the temperature reached at a given depth of concrete and to determine the flexural strength at such elevated temperatures. In [18], the paper clarify the impact of fire on steel reinforcement in reinforced concrete structure at elevated temperature and analyzed using three dimensional(3D) finite element method.

In [17], the paper explain multi-span RC beam exposed to fire in theory and numerical form. The paper [15], study the mechanical behavior of RC continuous members after exposure to fire including 5 RC continuous slab after exposure to fire including 7 RC beams carried out content f test including loading ,heating in ISO standard and post-fire loading. The result indicates that increasing of exposure time, the loss of bending rigidity is proved larger than that of the bearing capacity because different in size the slab were subjected to more severe damage than the beams under the same heating condition.

The paper [14] shows the behavior of RC L-beam and T-beam under fire study using finite element(ANSYS) method. result shows that type of exposure and the number of sides exposed to fire is having a great effect in the fire resistance of beams.

In [13], rehabilitation effect on fire damaged high concrete beams using experimental and analytic methods. In the experiments, flexural specimens with high strength concrete are exposed to high temperatures according to ISO 834 standard time temperature curve. From four-point loading test, results show that maximum loads of the rehabilitated beams are similar to or higher than those of the non-fire damaged RC beam. In addition, structural analyses are performed using ABAQUS 6.10-3 with same conditions as experiments to provide accurate predictions on structural and mechanical behaviors of rehabilitated RC beams. The parameters are the fire cover thickness and strengths of repairing mortar. Analytic results show good rehabilitation effects, when the results predicted from the rehabilitated models are compared to structural behaviors of the non-damaged RC beams. In the paper [3] illustrated effect of loading and beam size on the structural behavior of RC beam under and after fire. Load level, cross-sectional size, temperature are parameter of the structural element and performed using experimental and analytic. The result shows that temperature. Stiffens, and ductility of the fire-damaged beams are significantly influence by the load level, cross-sectional size and time exposed under fire. The paper [2] presents the effect of different face exposures: fully and partially on the behavior of normal strength of RC beams when exposed to fire. The results shows that cooling phase is critical in attaining maximum temperature in RC beams. Different face exposure and concrete strength significant affect the load at first cracking, serviceability deflection.

2.3 Review on the method of assessment of fire

Depending of the level of complexity and accuracy, method to assess fire resistance is classified in to four experimental, perspective, analytical and simplified [3].

2.3.1 Experimental analysis

Standard fire tests involve evaluating the structural performance of an element using a furnace. The fire temperature is controlled to follow a specific standard time temperature curve. The element is considered fire resistant if it satisfies specific load capacity and/or deformation criteria. The major disadvantages of standard fire tests are the cost and needed time. However, standard fire tests are the only valid method to assess deficiencies in construction detailing and to assess fire performance of new materials [23]. Results of fire tests are also essential to validate various numerical tools.

2.3.2 Perspective method

Prescriptive methods provide guidelines and tabulated data to specify minimum cross-section size and concrete cover to maintain the resistance of an element for a predefined fire exposure duration. They are mainly developed based on standard fire tests. Their main advantage is their cease of application. On the other hand, they tend to be conservative, and do not give engineers the flexibility to use irregular shapes and innovative solutions [23].

2.3.3 Analytical method

Advanced calculation method simply conducting a complete thermal and mechanical analysis to evaluate the resistance of a structural element exposed to fire. The thermal analysis is conducted using the principles of the heat transfer, which involves considering the temperature-dependent thermal properties of concrete [23]. The Finite Element Method (FEM) is considered the most common tool to carry out advanced fire resistance analysis.

Advanced calculation methods account for the continuous alteration of the thermal and mechanical characteristics of the materials, the boundary conditions, and the non-homogeneous distribution of the temperatures within the elements. Although advanced calculation methods provide a very realistic modelling, they require thorough background knowledge and the use of sophisticated computer programs.

2.3.4 Simplified methods

Simplified methods use the ambient-temperature design methods while taking into account the effects of fire [23]. They should provide structural engineers with reliable performance-based fire design tools.

2.4 Code recommendation for fire design of concrete beams

This section gives and over reviews different standard code design for fire resistance concerning on reinforced concrete beam.

2.4.1 Design of Rc beam according to ES and EN 1992:2015

Concrete cover is the distance between the surface of the reinforcement closest to the nearest concrete surface (including links and stirrups and surface reinforcement where relevant) and the nearest concrete surface. And it is essentials for four primary reasons (slab or beam).

- To bond the reinforcement to the concrete so that the two elements act together. The efficiency of the bond increases as the cover increases.
- To protect the reinforcement against corrosion.
- To protect the reinforcement from strength loss die to overheating in the case of fire.

Additional cover sometimes is provided on the top of slabs, particularly in garages and factories, so that abrasion and wear due to traffic will not reduce the cover below that required for structural and other purposes. Rather than giving the minimum cover, the tabular method is based on nominal axis distance, see fig.5 this is the distance from the center of the main reinforcing bar to the surface of the member. The designer should ensure that,

Concrete cover according to EN 1992-1-1 and EN 1992-1-2 The nominal cover is defined as a minimum cover C_{min} plus an allowance in design for deviation ΔC_{dev} ,

$$\mathbf{C_{nom}} = \mathbf{C_{min}} + \mathbf{\Delta C_{dev}} \tag{2.1}$$

Where C_{min} should be set to satisfy the requirements below:

- Safe transmission of bond forces
- Durability
- Fire resistance

And ΔC_{dev} is an allowance which should be made in the design for derivation from the minimum cover. It should be taken as 10 mm, unless fabrication (construction) is subjected to a quality assurance system, in which case it is permitted to reduce ΔC_{dev} to 5 mm.

2.4.2 Minimum cover for fire resistance

Rather than giving the minimum cover, the tabular method is based on nominal axis distance. This is the distance from the center of the main reinforcing bar to the surface of the member.

The designer should ensure that,

$$\mathbf{a} \ge \mathbf{C_{nom}} + \hat{\mathbf{O}}_{link} + \hat{\mathbf{O}}/2$$
 (2.2)

Table 2.1. Minimum dimensions and axis distances for simply supported beams made with reinforced and pre- stressed concrete [12].

2.4.3 Euro Code

Euro code 1 Part 1-2: "Actions on structures exposed to fire" [9] regulates calculation models for the determination of load effects and temperature. The fire scenario is treated as "exceptional action" and does not need to be superimposed with other load, Independent exceptional actions. For the fire design, different time-temperature curves are provided for the determination of hot gas temperature.

Euro Code 2 Part 1-2: "Design of Concrete Structures – Structural Fire Design" [10] deals with the design of concrete structures for the case of fire. It states the design values for material properties and combination factors for actions and treats methods of the passive and structural fire precautions; active fire protection methods are not included. For the determination of a sufficient fire rating, Euro code 2 gives three alternatives of design methods.

2.4.4 ACI 216.1-07/ TMS 0216-07

Code requirements for determining the fire resistance of concrete and masonry assemblies For concrete structures, fire resistance can be achieved by providing the appropriate depth of structural element and thickness of concrete cover depending on their function. ACI 216.1 and AC1 318 provide tables with various assemblies of building materials and finishes providing specific fire endurance.

Fire resistance rating is measured in terms of hours of exposure to the standard fire defined by ASTM E119 (2012), e.g., the fire rating for siliceous aggregate concrete with a minimum equivalent thickness of five inches (127 mm) is two hours. Formulas are provided to calculate the equivalent thickness of non-uniform sections, such as ribbed or undulating panels, and sections consisting of multiple layers. The code also gives minimum cover thickness to protect pre-stressed or passive steel reinforcement against fire. Distinction is made between restrained and non-restrained members. Most cast-in-place or precast construction is restrained, whereas single spans and simply-supported end spans of multiple bays are unrestrained [2].

2.4.5 Behavior of concrete at elevated temperature

Based on the compressive strength; concrete is normally classified as,

- normal strength concrete,
- Ultra-strength concrete.
- high strength concrete

Fire represents one of the most severe risks to buildings and structures. While normal concrete is typically considered to be resistant against fire and high temperatures, the low permeability of high performance fiber reinforced concrete (HPFRC) may result in failure by explosive spalling at high temperatures. Explosive spalling is the process of concrete explosively breaking away as a result of elevated temperatures. Spalling reduces the cross section area of critical sections and may expose conventional steel reinforcement to high temperatures.

2.5 Heat and Temperature

All matter is made up of molecules and atoms which are always in different types of motion. The motion can be translating, rotating or vibrating which creates thermal energy. Therefore all matters have thermal energy and the level of motion defines heat of a matter. The more motion the atoms or molecules have the more heat they will have. All movement of atoms and molecules are not similar to each other, some move faster than others. Temperature is a definition to cope with this variety and unified it in theory. Temperature is an average value of energy for all the atoms and molecules in a given system and it is independent of how much matter there is in the system. It is simply an average of the energy in the system.

2.6 Heat transfer

Heat transfer takes place in three ways: Conduction, Convection and Radiation. Both conduction and convection require matter to transfer heat [17].

2.6.1 Conduction

Takes place in matter. Conduction is one way to transfer heat between substances that are in direct contact with each other. It is transmission of kinetic energy among the molecules without matter transport. It is possible to classify matters according to the rate of heat transfer by conduction and define matters to be a good conductor or less conductor. The better the conductor, the faster heat will be transferred. For example metal is defined as a good conductor because heat transfer faster. Conduction occurs when a substance is heated, particles will gain more energy, and vibrate more. These molecules then bump into nearby particles and transfer some of their energy to them. This then continues and passes the energy from the hot end (more energetic particles) down to the colder end (less energetic particles) of the substance due to energy gradient. Conduction takes place in solids, liquids and gases.

2.6.2 Convection

One other way for heat transmission is Convection. Thermal energy can be transferred from hot places to cold places in fluids or gases due to bulk or macroscopic motion. Convection occurs when warmer areas of a liquid or gas rise to cooler areas in the liquid or gas. Cooler liquid or gas then takes the place of the warmer areas which have risen higher. This results in a continuous circulation pattern. Water boiling in a pan is a good example of these convection currents. Another good example of convection is in the atmosphere.

2.6.3 Radiation

Radiation is a method of heat transfer that does not rely upon any contact between the heat source and the heated object as is the case with conduction and convection. Heat can be transmitted through empty space by thermal radiation often called infrared radiation. Energy emitted by matter due to changes in electron configuration that results in changes in energy via electromagnetic waves or photons. No mass is exchanged and no medium is required for its propagation. Radiation is propagation of electro-magnetic waves in vacuum or in transparent matters. Examples of radiation is the heat from the sun, or heat released from the filament of a light bul.

2.7 Fire modeling as temperature

The time-temperature curve used in fire resistance tests is called the standard fire. Several models of time-temperature relationships are available for the simulation of fires for design purposes: The standard time-temperature curves from ASTM E119 and ISO 834 are compared in the figure below. They are seen to be rather similar. All other international fire resistance test standards specify similar time-temperature curves.

Figure 2.1: standard time–temperature curves from ASTM E119 and ISO 834 are compared [14]

Chapter 3

Research Methodology

3.1 Research design

The primary goal of this paper analysis the behavior of reinforced concrete beam subjected to fire. It focused on modeling of material properties at elevated temperature for both thermal and mechanical, for concrete, rebar and geometrical modeling of beam and finite element modeling of material in abacus.

3.2 Thermal Properties of Materials

Thermal properties of materials are those affect the temperature distribution or define the rate of heat transfer. Specific heat, Conductivity and density are the parameters required to determine diffusivity. These parameters also vary with temperature and duration of time for both materials, steel and concrete these parameters and its variation with respect to temperature are presented.

3.2.1 Thermal Properties of Concrete

Specific heat: The specific heat of concrete measures the energy required to raise one degree of temperature of one unit volume of concrete. According to EN 1992 1-2 the variation of specific heat of dry concrete (u = 0%) as function of temperature (valid for both siliceous and calcareous aggregates concrete).

| $(\theta) = 900$ | for $20^{\circ}C \le \theta \le 100^{\circ}C$ |
|--|---|
| $Cp(\theta) = 900 + (\theta - 100)$ | for $100^{\circ}C \le \theta \le 200^{\circ}C$ |
| $Cp(\theta) = 1000 + (\theta - 200)/2$ | for $200^{\circ}C \le \theta \le 400^{\circ}C$ |
| $Cp(\theta) = 1100$ | for $400^{\circ}C \le \theta \le 1200^{\circ}C$ |

Peak values of specific heat for different moisture contents are: $C_{ppeak} = 900$

For moisture content of 0% of concrete weight $C_{ppeak} = 1470$, for moisture content of 1.5% of concrete weight $C_{ppeak} = 2020$, for moisture content of 3% of concrete weight

Figure 3.1: Specific heat of concrete as function of temperature for three different moisture contents [10]

3.2.2 Thermal conductivity

Thermal conductivity is the ability of a material to conduct heat. It is defined as the ratio of the heat flux to temperature gradient. The EN 1992 1-2 defines the concrete's thermal conductivity (λ) between two boundary limits. The upper limit as function of temperature is given by:

 $\lambda_{c} = 2 - 0.2451 * (100\theta) + 0.0107 * (\theta/100)^{2} \text{ for } 20^{0}C \le \theta \le 1200^{0}C$ (3.1)

 $\lambda_{c} = 1.36 - 0.136 * (100\theta) + 0.0057 * (\theta/100)^{2} \text{ for } 20^{0}C \le \theta \le 1200^{0}C$ (3.2)

Figure 3.2: Thermal conductivity of concrete[10]

3.2.3 Thermal Elongation

The thermal strain of heated concrete (at temperature θ) is defined in relation to its initial length at ambient temperature (20⁰C) by equation 3.4 for siliceous aggregates concrete:

$$\epsilon_{\mathbf{c}}(\theta) = -1.8 * \mathbf{10} - 4 + 9 * \mathbf{10} - 6\theta + 2.3 * \mathbf{10} - \mathbf{11}\theta^{\mathbf{3}} \quad \text{for} \quad \mathbf{20^{0}C} \le \theta \le \mathbf{700^{0}C}$$
(3.3)

$$\epsilon_{\mathbf{c}}(\theta) = \mathbf{14} * \mathbf{10} - \mathbf{3} \text{ for } \mathbf{700^{0}C} \le \theta \le \mathbf{1200^{0}C}$$
(3.4)

Equation 3.6 defines the thermal strain for calcareous aggregates,

$$\epsilon_{\mathbf{c}}(\theta) = -1.2 * \mathbf{10} - \mathbf{4} + \mathbf{6} * \mathbf{10} - \mathbf{6}\theta + \mathbf{1.4} * \mathbf{10} - \mathbf{11}\theta^{\mathbf{3}} \quad \text{for} \quad \mathbf{20^{0}C} \le \theta \le \mathbf{805^{0}C}$$
(3.5)

 $\epsilon_{c}(\theta) = 12 * 10 - 3 \text{ for } 805^{0}C \le \theta \le 1200^{0}C$ (3.6)

Page 16

Figure 3.3: Thermal elongation of concrete with temperature [10]

3.3 Thermal Properties of reinforcing

3.3.1 Thermal elongation of reinforcing

Reinforcing steel:

$$\epsilon_{\rm s}(\theta) = -2.416 * 10^{-4} + 1.2 * 10^{-5}\theta + 0.4 * 10^{-8}\theta^2 \quad \text{for} \quad 20^{\rm o}{\rm C} \le \theta \le 750^{\rm o}{\rm C}$$
(3.7)

$$\epsilon_{\mathbf{s}}(\theta) = \mathbf{11} * \mathbf{10^{-3}} \quad \text{for} \quad \mathbf{750^{0}C} \le \theta \le \mathbf{860^{0}C}$$
(3.8)

$$\epsilon_{\rm s}(\theta) = -6.2 * 10^{-3} + 2 * 10^{-5}\theta \quad \text{for} \quad 860^{0} \rm C \le \theta \le 1200^{0} \rm C$$
(3.9)

3.3.2 Specific heat

 $\mathbf{C_a} = \mathbf{425} + 7.73 * \mathbf{10^{-1}}\theta - \mathbf{1.69} * \mathbf{10^{-3}}\theta^2 + 2.22 * \mathbf{10^{-6}}\theta^3 \quad \text{for} \quad \mathbf{20^0C} \le \theta \le \mathbf{600^0C}$ (3.10)

$$C_a = 666 + 13002(738 - \theta)$$
 for $600^0 C \le \theta \le 735^0 C$ (3.11)

$$C_a = 545 + 17820(-731 + \theta)$$
 for $735^0C \le \theta \le 900^0C$ (3.12)

Page 17

$$C_a = 650 \text{ for } 900^0 C \le \theta \le 1200^0 C$$
 (3.13)

Figure 3.4: Variation of the specific heat of steel with temperature [10]

3.3.3 Thermal conductivity

The thermal conductivity of steel depends mainly on the composition of the material and decreases with increasing temperature. The thermal conductivity of steel is assumed to be high enough to allow the assumption that normal size sections have a uniform temperature throughout [14].

$$\lambda_{\mathbf{a}} = 54 - 3.33 * 10^{-2} \theta \quad \text{for} \quad 20^{0} \mathrm{C} \le \theta \le 800^{0} \mathrm{C}$$
 (3.14)

$$\lambda_{\mathbf{a}} = \mathbf{27.3} \quad \text{for} \quad \mathbf{800^0 C} \le \theta \le \mathbf{1200^0 C}$$
 (3.15)

3.4 Mechanical properties of Concrete

At elevated temperatures, the mechanical behavior of concrete is complex, involving strong non-linearity, different failure mechanisms under compression and tension (crushing or cracking), and other temperature-dependent effects such as thermal expansion and . Concrete temperature-dependent mechanical properties, including compressive and tensile strength, modulus

Figure 3.5: thermal conductivity of steel with different temperature [10]

of elasticity, Poisson's ratio and component of strain are discussed in this section.

3.4.1 Compressive strength of concrete

Compressive strength of concrete decreases with increasing of temperature. It can be seen that concrete with siliceous aggregates undergoes a rapid loss in strength at a temperature around 450° C, where temperature around 700° C[17] The strength-temperature relationship defined in Euro code [16] for concretes with siliceous and calcareous aggregates is plotted in figure below.

3.4.2 Tensile strength of concrete

The tensile strength of concrete also decreases with increasing temperatures. Compared to the compressive strength, the tensile strength shows a greater relative decrease and thus, is more responsive to the effects of temperature. The tensile strength is affected by the mix portions and significantly by the type of aggregate.

3.4.3 Poisson's ratio

Based on the test data, the Poisson's ratio of concrete is taken as 0.20 at 20^{0} C and to remain constant until 150^oC. Beyond the latter temperature, the Poisson's ratio is assumed to decrease linearly to 0.1 at 400^oC and to

Figure 3.6: Ratio of compressive strength according to euro code2 [10]

further decrease linearly down to zero at 1200° C. In this paper constant Poisson's ratio 0.2 has been used.

3.4.4 Concrete density

The density of concrete is taken to have constant value of 2400 $\rm Kg/m^3$ for all temperature change.

3.4.5 Components of strain

 $\epsilon = \epsilon_{\mathbf{th}}(\mathbf{T}) + \epsilon \sigma(\tilde{\sigma}, \sigma, \mathbf{T}) + \epsilon_{\mathbf{cr}}(\sigma, \mathbf{T}, \mathbf{t}) + \epsilon_{\mathbf{tr}}(\sigma, \mathbf{T})$ (3.16) Where $\epsilon = \text{total strain}, \quad \epsilon_{tr} = \text{transient strain}$ $\epsilon_{th} = \text{thermal strain}, \quad \mathbf{T} = \text{temperature}$ $\epsilon \sigma = \text{stress related strain}, \quad \sigma = \text{stress}$ $\epsilon_{cr} = \text{creep strain}, \quad \tilde{\sigma} = \text{Stress history}$

3.4.6 Modulus of elasticity

During heating the modulus of elasticity decreases. This is due to the breakage of bonds in the microstructure of cement paste as well as to the increase of short-time creep at increasing temperature.

$$\mathbf{E_{cT}} = \mathbf{1.0} * \mathbf{E_c} \quad \text{for} \quad \mathbf{20^0 C} \le \theta \le \mathbf{100^0 C} \tag{3.17}$$

Figure 3.7: Reduction in tensile strength according to euro code [10]

$$\mathbf{E_{cT}} = (1.015 - 0.00154\theta + 2 * 10^{-7}\theta^2 + 3 * 10^{-10}\theta^3)\mathbf{E_c} \quad \text{for} \quad 100^0 \mathbf{C} \le \theta \le 1000^0 \mathbf{C}$$
(3.18)

$$\mathbf{E}_{\mathbf{cT}} = \mathbf{0} \quad \text{for} \quad \theta \ge \mathbf{1000^0 C} \tag{3.19}$$

3.5 Mechanical properties of steel

3.5.1 Strain component

The total strain of steel can be calculated as the sum of three strain components similar to the total strain of concrete according the following formula,

$$\epsilon = \epsilon_{\mathbf{th}}(\mathbf{T}) + \epsilon \sigma(\sigma, \mathbf{T}) + \epsilon_{\mathbf{cr}}(\sigma, \mathbf{T}, \mathbf{t})$$
(3.20)

Where

Page 21

| $\epsilon = \text{total strain},$ | ϵ_{cr} =creep strain |
|---|-------------------------------|
| $\epsilon_{th} =$ thermal strain, | T = temperature |
| $\epsilon \sigma = \text{stress related strain},$ | $\sigma = \mathrm{stress}$ |

3.5.2 Steel density

The density of steel is remaining essentially constant with temperature and therefore is assumed to be 7850 $\rm kg/m^3k.$

3.5.3 Deformation properties of materials

Thermal expansion, creep strain are deformation properties of materials are dependent on the chemical composition, aggregate type and chemical reactions during heating in the concrete and for steel the thermal expansion depends on the molecule composition of the steel bars.

3.5.4 Thermal expansion of concrete

When concreted exposed to fire it goes under expansion. The thermal expansion varies with temperature. The thermal expansion of concrete increases from zero at room temperature to about 1.3% at 700° C and then generally remains constant through 1000° C. This increase is substantial in the 20 – 700° C temperature range and is mainly due to high thermal expansion resulting from constituent aggregates and cement paste in concrete. Thermal expansion of concrete is complicated by other contributing factors such as additional volume changes caused by variation in moisture content, by chemical reactions (dehydration, change of composition), and by creep and micro-cracking resulting from non-uniform thermal stresses. In some cases, thermal shrinkage can also result from loss of water due to heating, along with thermal expansion, and this might lead to the overall volume change to be negative, that is, shrinkage rather than expansion.

3.5.5 Thermal expansion of steel

Steel rebar show elongation behavior under elevated temperatures. If the grades of rebar were higher it shows less elongation and it depends on ductile behavior of the steel. At high temperatures the steel reinforcement show ductile behavior and it causes increase in deflection of the structural members. The elongation ratios were increased up to 300° C, while the material becomes brittle with decrease of the elongation values.

Figure 3.8: Thermal expansion of concrete [10]

3.6 Finite Element Modeling

3.6.1 Abacus software

The commercial finite element software Abaqus[]is the most widely used software in the academic research of material and geometric nonlinear analysis due to the flexibility that it provides for the users with numerous options for materials models, analysis and solutions techniques.

Material modeling in ABAQUS

The 3D BEAM reinforced concrete was modeling using ABAQUS 6.1 software version. The concrete beam modeled using solid element, for heat transfer analyses. There are three type of modeling in abacus. The smeared crack model, The brittle cracking model, The concrete damaged plasticity model. concrete damage plasticity used for this study.

Concrete damage plasticity

The CDP model needs a complete stress-strain curve of concrete under compression to define the compressive behaviour. The stress-strain curve can be defined beyond the ultimate stress into the strain softening region. Two parameters are required to be defined in the tabular format, namely compressive stress σ_c (i.e., yield stress) and the inelastic strain ϵ_{cin} .

Figure 3.9: Thermal elongation of steel [10]

Creating numerical model

The section was modeled in Abaqus CEA software in order to find the temperature distribution over the cross section in different times of exposure. The software program requires number of parameters and characteristics inputs to analyze the problem. The following steps have been used to produce the model and read the results.

Part In Abaque there is a section which called "Part". In this section model can be drawn by knowing the geometry of the beam. The coordinates of the points were determined in millimeter unit, therefore in all other sections, if it is referred to length, the unit is considered to be in millimeter.

Property

In this part both steel and concrete property is fill based on euro code and previous research. Density conductivity, specific heat, concrete damaged plasticity, expansion coefficient, modulus of elasticity poisons ratio was based on euro code, and geometrical model based on the previous experimental research.

Reinforcement steel

Steel is a homogeneous material and the stress-strain behavior can be

Figure 3.10: Concrete beam layer FEM model

assumed to be identical in tension and compression. Steel bars in reinforced concrete members are normally long and relatively slender and, therefore, they can be generally assumed to be capable of transmitting axial forces only.in this study three different bar diameter are used to investigate the effect of bar diameter on different temperature.

Assembly Modeling between Concrete and Reinforcing

The concrete plate and beams are constrained by the 'assembly' module 'create instance and translate instance' command. The translate instance command in abaqus is used to bind two types of element. this section, beam (part 1) and Steel bars (part 2) are assembled together. In order to assemble these two parts, firstly it is needed to extract holes corresponding to steel bars from the beam. Then, by adding steel bars to part 1 in the positions of holes the model become complete and new part will be created (Part 3). At the end, it is better to make part 3 dependent in order to have better meshing.

Figure 3.11: Steel layer FEM model

Figure 3.12: Stirrup and steel layer FEM modell

Figure 3.13: Reinforced concrete beam layer FEM model

Interaction

Interaction is the part that the property and characteristic of fire will be defined. Surface radiation and surface film condition has been defined.

Figure 3.14: Interactions input to FEM model

Mesh size and Element type

As an initial step, the finite element analysis requires meshing of the model. Hence, the model is divided into number of small elements. After the application of the load, the stress and the strain are calculated at integration

points of these elements. The approximate mesh size used in this study is 50. The element types used for thermal analysis were 3D eight-node continuum (DC3D8). The stress element used were C3D8R. This is defined as a three-dimensional (3D), continuum (C), hexahedral and an eight-node brick element with reduced integration (R).

Figure 3.15: Mesh of RC beam layer

Figure 3.16: Side view of RC beam

Load, Boundary condition and predefined field

The heat transfer analysis was carried out by applying the ISO834 temperature time curve into node of the bottom and two side of beam as amplitude tabulated data and for unexposed side Heat transfer analysis is independent of support boundary condition since no displacement is involved. Three loading steps were used for structural analysis. The first step is initial loading, $25C_0$ magnitude were applied on beam. The second steps were the output of thermal analysis which is applied as predefined load on beam. The third steps were mechanical loading; mechanical load was applied on beams at magnitude of 24.688 KN/mm² in the negative Y-direction. Boundary condition used were, $U_x=U_y=U_z=0$ on left support and $U_y = 0$ for right support. Rotation at both support and U_x , U_z at right support is non-zero.

Distributed load on beam=24.688 KN/mm² pressure = 24688/0.2 = 123440/0.2 is width of the beam.

Figure 3.17: Loading and boundary condition RC beam

Steps of analysis in ABAQUS

In this part, the method of analyzing and its required parameters were defined. Since the model is carrying load and also exposed to fire, the method has been chosen is "coupled temp-displacement". Time period is 7200 seconds and was used transient response. The outputs are "stresses", "stress misses", "deflection", "Nodal temperature (NT)", for every increments.

The tensile strength of concrete also decreases with increasing temperatures. Compared to the compressive strength, the tensile strength shows a greater relative decrease and thus, is more responsive to the effects of temperature. The tensile strength is affected by the mix portions and significantly by the type of aggregate.

Thermal analysis: The Euro code temperature-dependent thermal properties (thermal conductivity, specific heat, density) of concrete and reinforcing steel are built into the program.

Mechanical analysis: Mechanical analysis is the second step of analysis conducted in this study to determine structural response of concrete beam exposed to fire. Finite Element software Abaqus is used to predict the structural response to the temperature increase. The nodal temperatures from the time varying nodal temperature data from the heat transfer analysis is applied as a boundary condition on the structural response model analysis. Nonlinear temperature-dependent material property (Poisson's ratio, compressive strength, tensile strength, Young's modulus, and yield strength) in accordance with Euro code 2 [15] and is constant along the length of the beam element.

Geometrical modeling: The structural system modeled in this study is simply supported beam. The dimensions were length 5 meter, depth 400 mm and width 200 mm.RC beam reinforced bar used were 16 .diameter and top and bottom of beam respectively for validation. But for other analysis 12, 14 16 mm diameter was used in different temperature and duration of time.

Chapter 4

Result and Discussion

4.1 Overview of the FEA result

In this chapter, the result and the model is displayed in the figure and diagram. From the mechanical analysis, the results focus on mid-span deflections, stress along x (s11) in concrete for RC beam. Each model was considered in a heat transfer analysis and mechanical analysis. All results that represent temperature data origins from the heat transfer analyses, while all other data is taken from the mechanical analyses. Finite element validations are discussed to check the accuracy of present FE model.

4.2 Validation of the FE model

The dimensions and reinforcement details of the beam are in the shown in the Figure below The reinforcing steel had 240 MPa and 380 MPa of yield stress and tensile strength, respectively and 210000 MPa modulus of elasticity. The concrete cube strength is 23.1 MPa and 29000 MPa modulus elasticity of concrete. During the test slab with thickness 80 mm was placed over the beam and distributed load of 300 kg/m² was applied on the top slab. The total load acting on the beam consisted. The distributed load and self-weight of the slab. During heat transfer the beam is subjected to ISO834 on two side and bottom of beam. And for unexposed surface and initial load step 27^oC was applied. All material input and models was done with the procedure according to the present FE model. Temperature verses deflection and temperature versus exposure time of the beam selected for validation.

4.3 Results of RC beam

Thermal analysis is used for the determination of nodal temperature distribution along the cross section of the beam. The Geometrical modeling type of beam with the same dimension is selected. and the same thermal analysis was conducted for the beam. The value of nodal temperature is uniform longitudinally and different along center of the beam. because of concrete cover. The results from ABAQUS are presented in table 4.1 at different point of the beam along cover and diameter of bar for fire exposure of 30, 60, 90, 120 minutes. However the concrete cover and bar diameter are used simultaneously for modeling of RC beam. Because euro code recommend concrete cover for different diameter of bar, but not specify the effect of concrete cover on different temperature and duration of time.

| Node | Time in minute | Temperature |
|------|----------------|-------------|
| 2717 | 30 | 830.127 |
| | 60 | 930.801 |
| | 90 | 994.857 |

Table 4.1: Summary of values of nodal temperatures for different time of exposure

Thermal analysis nodal temperature-time curves were obtained. As expected the result indicated that as time of fire exposure increased temperature distribution value also increased. As shown on Table 4.1 above at different node different temperature is obtained for different time of exposure.

Figure 4.4: Varation of stress with temperature and concrete cover

From thermal analysis nodal as concrete cover increased the value of nodal temperature decreased along the center of the beam, for different fire exposure duration different values of nodal temperature obtained at the same node. As can be seen, temperature is maximum at exposed surface of temperature of beam and minimum at unexposed side. As time increased nodal temperature also increased As the time of exposure increased nodal temperature also increased and maximum temperature occurred at the surface exposed to fire whereas minimum temperature at internal section of beam. As shown in the Figure 4-3 concrete cover increased the value of stress increased, When the concrete cover 30 the stress along the center of the beam is highly increase and the concrete cover is 25 the stress along the center of the beam is decrease half of 30 concrete cover.

Figure 4.5: Temperature variation along concrete cover

As concrete cover increased the value of nodal temperature decreased along the center of beam. For different fire exposure duration, different values of nodal temperature obtained at the same node. As its seen temperature is maximum at exposed surfaces of beam and minimum at unexposed side. As time increased nodal temperature also increased. Numerical value is set in appendix D.

Figure 4.7: Screen shot of thermal analysis result

Page 36

Vertical deflection of RC beam

The vertical deflection of the RC beam at mid span is increased as the time of exposure to fire increased. At exposure of 60 minute vertical deflection of beam increased highly by more than half of deflection at 30 minute. As exposure time increased to 90 and 120 minute the value of deflection added, but not increased with the rate at 30 and 60 minute. And as temperature increase vertical deflection at mid span increased. See appendix D-2.

Chapter 5

Conclusions and Recommendation

5.1 Conclusion

Anon linear 3D FE model was developed in this study and validated the experimental program conducted by [10] as can be seen from the previous section. And it is good agreement between the measure experimental and predicted FE model. ABAQUS different steps of modeling has been conducted such as geometry, Material properties, mesh generation, and element selection, creating boundary condition, and step of analysis.Both thermal and mechanical properties of material are defined according to euro code and previous researches based on this researches the following conclusion are follow:

- When the concrete cover becomes 30, the stress along the center of the beam increase; when it becomes 25 and 20, the stress along the center of the beam will be much lower than that of the above cover.
- The result indicates that, as time of fire exposure increase nodal temperature value of RC beam also increases.
- Thickness of Concrete cover is increase the stress at the middle of the beam is increase. The diameter of the bar is direct relationship to concrete cover if the diameter of the bar is increase the thickness of concrete cover also increase.
- Deflection in RC beam at 60 minute increased by 1.49 times the deflection at 30 minute and slowly increased at 90 and 120 minute.
- 3D sequential fully coupled thermal stress analysis simulation is capable of determine the response of concrete beam exposed to fire

5.2 Recommendation

As seen from this research, Exposure to fire or elevated temperature of structural element is an extreme condition that leads to change of structural behavior so, The following recommendations are presented in order to develop and improve current findings.

- The beams were tested under the effect of concrete cover and bar diameter with different period of time with different nodal temperature. More research is needed to determine the effect of boundary condition and different loading.
- More variable should be considered to achieve more specified result. such as boundary condition, type of loading.
- Fire resistance rating of structural elements and/or whole structure of different type of structure should be consider such as RC, composite structure and steel structures.
